The value of experience in the pressure measurement field

The accuracy and reliability of Negretti and Zambra instruments for the measurement and control of pressure are the result of many years' experience and the closest co-operation with the scientists and industries who use them.
Hence the supremacy of Negretti and Zambra instruments in the field of pressure measurement as in many others

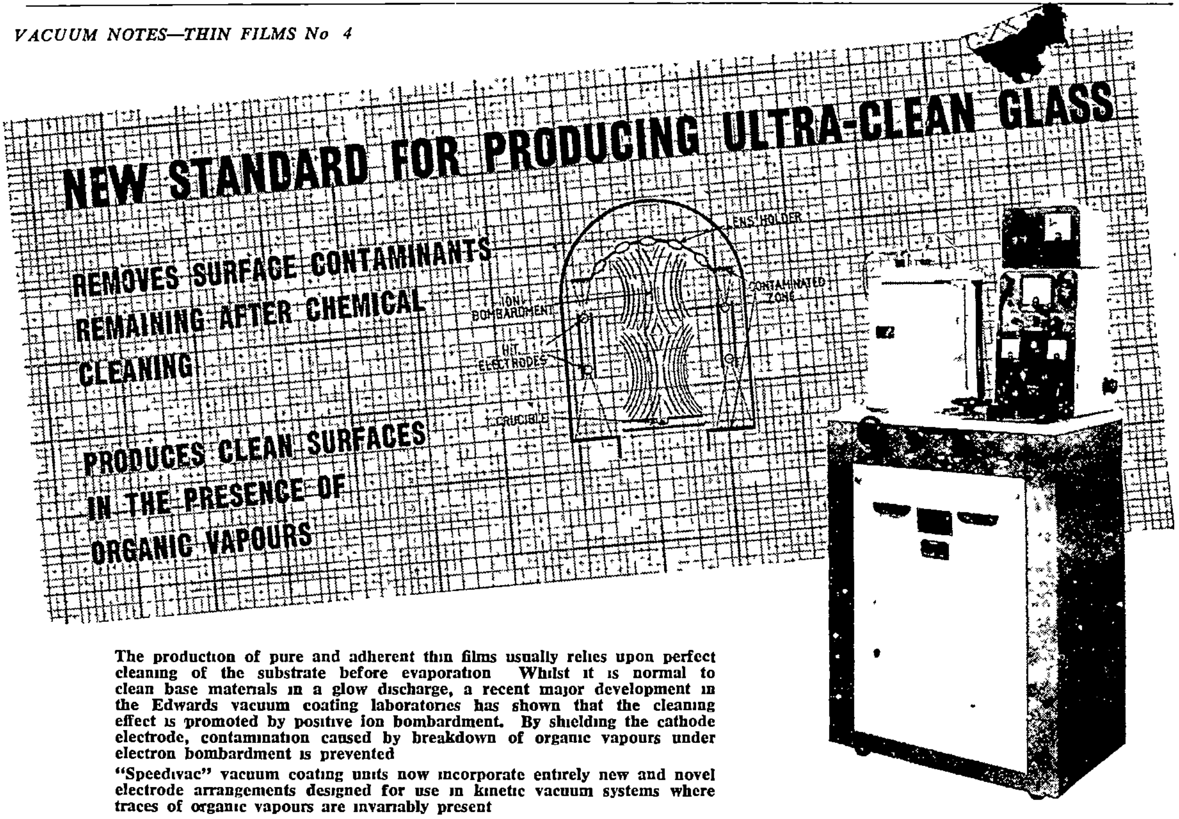
VACUUM NOTES—THIN FILMS No 4

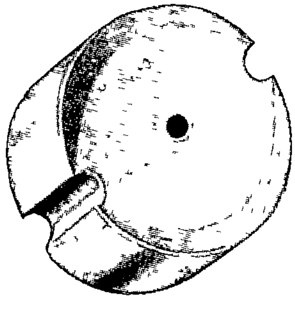


NEW STANDARD FOR PRODUCING ULTRA-CLEAN GLASS
REMOVES SURFACE CONTAMINANTS REMAINING AFTER CHEMICAL CLEANING
PRODUCES CLEAN SURFACES IN THE PRESENCE OF ORGANIC VAPOURS
LENS HOLDER
CONTAMINATED ZONE
ION BOMBARDMENT
H.T. ELECTRODES
CRUCIBLE

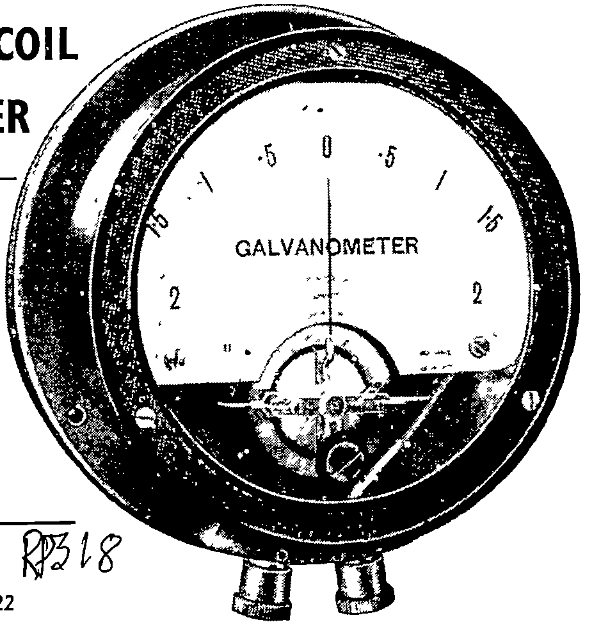
The production of pure and adherent thin films usually relies upon perfect cleaning of the substrate before evaporation Whilst it is normal to clean base materials in a glow discharge, a recent major development in the Edwards vacuum coating laboratories has shown that the cleaning effect is promoted by positive ion bombardment. By shielding the cathode electrode, contamination caused by breakdown of organic vapours under electron bombardment is prevented

"Speedivac" vacuum coating units now incorporate entirely new and novel electrode arrangements designed for use in kinetic vacuum systems where traces of organic vapours are invariably present

EDWARDS HIGH VACUUM LTD., MANOR ROYAL, CRAWLEY, SUSSEX, ENGLAND



MUREX 'SINCOMAX' PERMANENT MAGNETS *are used in this* CROMPTON PARKINSON 120° MOVING COIL GALVANOMETER



The use of the 'Sincomax' technique in producing this co-axial magnet enables the 120° arc to be obtained easily The combining of the soft iron and magnetic material provides a stable, high energy product in small volume.
For technical information on the design, performance and characteristics of Murex Permanent Magnets write for a copy of the Magnet Catalogue.

Quantitative Infrared Intensity Measurements to 0·1% accuracy!

An account has appeared of a procedure* by which the Unicam SP 100 Infrared Spectrometer (standard single prism monochromator) can be adjusted to give routine intensity measurements to an accuracy of 0 1 % transmission The description shows that this accuracy is maintained to at least 2 per cent transmission levels Reliable results to this degree of accuracy are particularly important to the analytical chemist concerned with precise quantitative measurements The exceptional photometric accuracy of the Unicam SP 100 makes possible this high performance over the whole range of infrared work With the SP 130 Grating accessory, accurate intensity measurements at high resolution become a routine procedure

**Spectrovision No 6*

Mixture of α, β, γ-PICOLINE and 2 6 LUTIDINE (15 49 mg/g)

Absorption peaks

A γ - PICOLINE (792 cm^{-1})
B β - PICOLINE (781 cm^{-1})
C 2,6-LUTIDINE (768 cm^{-1})
D α - PICOLINE (746 cm^{-1})

This spectrum, taken in a 0 28 mm cell with cyclohexane solvent using single monochromator (rocksalt optics), is typical of those being used regularly for high-accuracy intensity measurements in the analytical laboratories of The Midland Tar Distillers Ltd (to whom grateful acknowledgement is made)

SP. 100 Infrared Spectrometer

The Unicam S 150 High Temperature Powder Camera makes possible the study of material by X-ray diffraction photography at all temperatures up to 1400°C

The camera is suitable for capillary or fibre specimens rotated as for normal Debye-Scherrer cameras, and for small block specimens, which may be scanned vertically and oscillated for glancing-angle and back-reflection photographs

The instrument is fully described in an illustrated brochure, which will be sent free of charge on request

DIFCO microbiological reagents and media

Bacto-Dehydrated Media for Microbiological Assay of
VITAMINS and AMINO ACIDS

These *media* contain all the necessary nutriments for the growth of specified test organisms for the microbiological assay of vitamins and amino acids except for the component under assay These basal media require only the addition of specified increasing amounts of the vitamin or amino acid being assayed to obtain a growth response which may be measured by acidimetric or turbidimetric methods for the construction of standard curves The vitamin or amino acid content of the material under assay is determined by adding appropriate concentrations of the test substance to the basal medium and comparing the growth response obtained with that of the standard

BACTO-RIBOFLAVIN ASSAY MEDIUM
BACTO-NIACIN ASSAY MEDIUM
BACTO-THIAMIN ASSAY MEDIUM
BACTO-PANTOTHENATE ASSAY MEDIUM
BACTO-B_{12} ASSAY MEDIUM USP
BACTO-CS VITAMIN B_{12} AGAR
BACTO-FOLIC ACID ASSAY MEDIUM
BACTO-PYRIDOXINE ASSAY MEDIUM
BACTO-BIOTIN ASSAY MEDIUM
BACTO-CHOLINE ASSAY MEDIUM
BACTO-CF ASSAY MEDIUM
BACTO-TRYPTOPHANE ASSAY MEDIUM
BACTO-LEUCINE ASSAY MEDIUM
BACTO-METHIONINE ASSAY MEDIUM
BACTO-LYSINE ASSAY MEDIUM
BACTO-ISOLEUCINE ASSAY MEDIUM
BACTO-ARGININE ASSAY MEDIUM
BACTO-TYROSINE ASSAY MEDIUM
BACTO-CYSTINE ASSAY MEDIUM

The *method* employed in carrying stock cultures of the test organisms and preparing the inoculum for microbiological assay is important The following media have been developed especially for carrying stock cultures and for preparation of the inoculum

BACTO-MICRO ASSAY CULTURE AGAR
BACTO-MICRO INOCULUM BROTH
BACTO-B_{12} CULTURE AGAR USP
BACTO-B_{12} INOCULUM BROTH USP
BACTO-NEUROSPORA CULTURE AGAR

BACTO-VITAMIN FREE CASAMINO ACIDS, dehydrated, is an acid hydrolysate of vitamin-free casein prepared especially for laboratories investigating microbiological assay of vitamins

Scintillators in 5 forms

Scintillators in five forms are now available from Nash and Thompson Ltd

CRYSTALS
Anthracene, Stilbene, Diphenylacetylene, in discs and cylinders

PLASTICS
N 11 and N 11-X-ray, high sensitivity, high transmission polyvinyl toluene based.

LIQUIDS
Ready made, sealed in glass containers to your specification, or as scintipaks

SCINTIPAKS
Accurately mixed dry constituents sealed in polythene envelopes, ready for dissolving in a suitable solvent as required

POWDERS
Scintillation purity chemicals for crystal growing experiments, and the manufacture of special scintillators

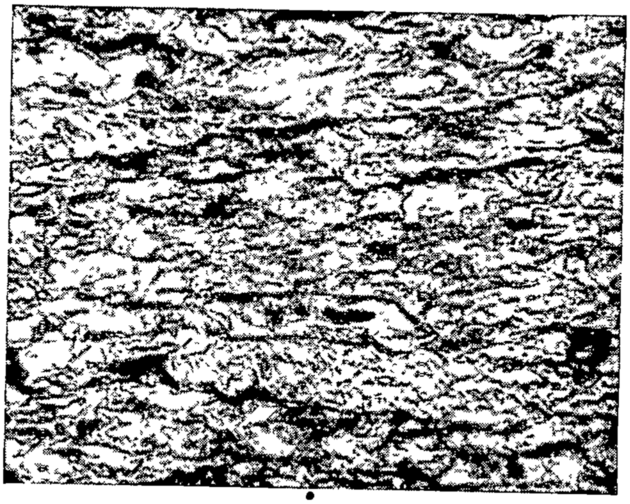
For quality control of metals

The introduction of pre-determined quantities of thorium into tungsten greatly increases the emission of radio-valve components and transistors It also provides a more stable arc between electrical contacts

But these are only two of the many advantages Thoriated tungsten produced by The Tungsten Manufacturing Company helps to ensure greater reliability and increased performance in many fields from the manufacture of simple ignition systems for road vehicles to research into the control of nuclear reactions

Strict control over the quality of the thoriated tungsten is maintained at all stages of manufacture, and regular checks by photomicrography form a major part of this control For this purpose The Tungsten Manufacturing Company relies on 'Kodak' 0 250 Plates



1½% thoriated tungsten rod Longitudinal section × 500 0 250 Plate

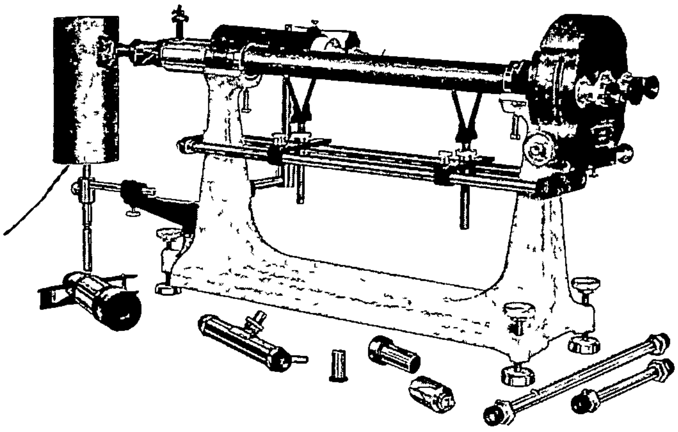
PRECISION BS INSTRUMENTS

Polarimeter Model A

This instrument gives the highest degree of accuracy with divided circle on glass reading to 0·01 degree



Circle centre on ball bearings.
Easily removable trough.
Divided drum replacing verniers
Stationary observation telescope
Circle reader enlarging image of scale
Slow motion adjustment always in action
Suitable, with additions, for measurement of rotatory dispersion

This polarimeter has been supplied in large numbers both in this country and abroad and has always been acclaimed as being of advanced design and workmanship

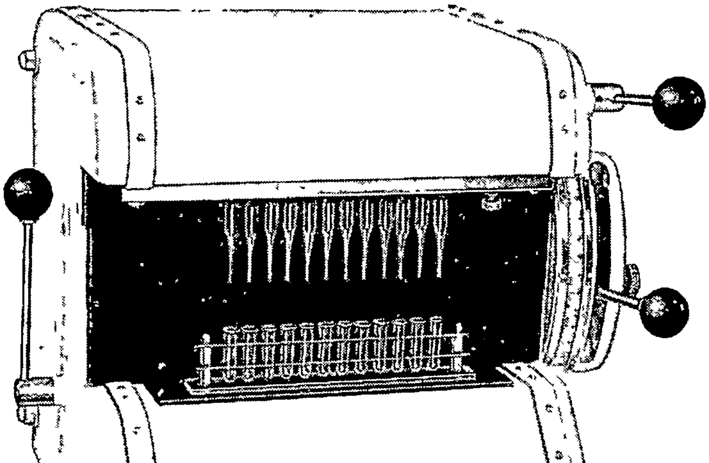
A NEW INSTRUMENT BY NASH AND THOMPSON

THE SEROLOGICAL DISPENSER



This automatic dispenser for multiple titrations was developed at the Lister Institute of Preventive Medicine for routine serological investigations The apparatus allows the performance of up to 12 titrations in a single operation with even less manipulation than required for a single test by conventional technique

- **Volume range 0 01 ml to 1 0 ml**
- **Automatic loading of up to 12 pipettes**
- **Simultaneous dispensing from all pipettes**
- **Accuracy better than that obtainable using Grade 'B' British Standard serological volumetric glassware**

The instrument has possible applications in micro-chemistry and micro-biology For further information write to

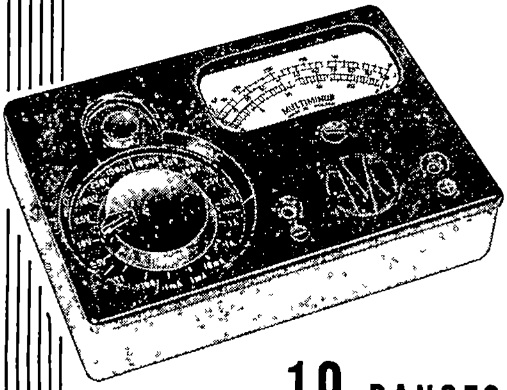
The
MULTIMINOR

A pocket-size instrument for the Laboratory worker



19 RANGES

THIS splendid AVO Instrument has been developed to meet a definite demand for a sturdy pocket-size multi-range test meter at a modest price, suitable for use on modern electronic apparatus as well as for radio and television receivers, motor vehicles, and all kinds of domestic appliances and workshop equipment.

Readings are obtainable quickly and easily on a very open scale, and range selection is by means of a robust clearly marked rotary switch of the characteristic AvoMeter type Measurements of A.C and D.C. Voltage, D.C. Current, and Resistance are made by means of only two connection sockets.

Write for free illustrated leaflet

D C. Voltage	A.C. Voltage
0— 100mV	0— 10 V.
0— 2 5V	0— 25 V
0— 10 V	0— 100 V
0— 25 V	0— 250 V
0— 100 V.	0—1000 V
0— 250 V	
0—1000 V	

Resistance	D C Current
	0—100μ A
	0— 1mA
0—20,000Ω	0— 10mA
0—2 MΩ	0—100mA
	0— 1 A

Sensitivity
10,000 ohms per volt on D C voltage ranges
1,000 ohms per volt on A C voltage ranges.

Accuracy
On D C 3% of full scale value
On A C 4% of full scale value

To meet special requirements, instruments can be supplied to a higher degree of accuracy for a small additional charge

Pocket Size 5⅝ x 3⅜ x 1⅝ inches
Weight 1 lb approx

List Price

£9:10s.

complete with Test Leads and Clips

Two new 'Kodak' recording papers

RP.12 for records in seconds

RP.35 for 50% more paper

Recent improvements in the design of recording equipment have done much to speed the supply of vital information to research engineers Keeping pace with these improvements, Kodak have introduced two new photographic materials that greatly increase the usefulness of recording instruments They are

'Kodak' RP.35 High-Speed Thin-Base Recording Paper,

which combines the excellent photographic characteristics of 'Kodak' RP 30 paper with a thinner base, allowing 50% more paper to be loaded into the recording instrument

'Kodak' RP.12 Print-Out Recording Paper,

which produces a visible image in a few seconds, without processing

Full details of these new recording materials will be sent on request

SP.700 Recording Spectrophotometer 186mμ-3·6μ

First production models of the new Unicam SP.700 Recording Spectrophotometer have now been installed and are in daily use. To the busy analytical laboratory that depends upon spectroscopic methods—ultraviolet, visible or near infrared—the SP.700 offers new standards of speed and flexibility with performance of the highest order. The instrument is well-suited to specialist techniques calling for the highest levels of precision and stability—e.g reaction studies at fixed frequency.

THIOGEL

Schwarz

Thiolated Gelatin

THIOGEL is the first in a series of thiolated proteins to be offered by Schwarz Laboratories, Inc The thiolation of gelatin, addition of free sulfhydryl (SH) groups, enlarges the molecular structure and remarkable new properties are developed

One of the properties of THIOGEL is its ability to form a heat stable gel rapidly, without chilling The gel formed does not redissolve in boiling water

Possible applications of THIOGEL:

Pharmacy:
Vehicles for pharmaceuticals, preparation of absorbent surgical sponges, protective agent against radiation

Cosmetics:
For hair setting bases

Biochemistry:
For enzyme stabilization

Photography:
Special emulsions for developing and printing

Printing:
For fast setting printing processes

Papers and Textiles:
For special finishes and coatings

SAFETY IN THE LABORATORY

J. NEWTON FRIEND, D.Sc., F.R.I.C. 6s

"This is a useful, pocket-size handbook on laboratory organisation with particular reference to safety The book is addressed to teachers and laboratory attendants and contains much admirable advice on laboratory services, storage of apparatus, locker equipment, and bench and side reagents, In addition there are chapters on fire-fighting and first-aid
"There is an adequate index for quick reference and the place for the book is in the pocket of the laboratory overall "

FUNDAMENTAL RESEARCH IN BRITAIN

IT is well known that there has for some time been a serious conflict of opinion as to whether Britain should undertake a programme of space research Such a project has been strongly supported by some scientists and, as would appear from the tenor of his replies to questions on the subject in the House of Commons, is also favoured by the Minister of Supply Other scientists, however, are doubtful as to Britain's ability to spend sufficient resources on such a project to obtain a worth-while return without adverse effects on our scientific effort in other fields It has also been manifest from comments in the House of Commons that there is a strong body of opinion decidedly opposed to Britain entering on any such project merely because Russian and American scientists have done so, without the most careful consideration both of the probable return and the likely effect on our research effort elsewhere

The programme disclosed in the Prime Minister's statement in the House of Commons on May 12 seems unlikely to alarm those concerned about its effect on research effort generally Mr Macmillan said specifically that, while he could not give any figure for the cost of using a British rocket should it be decided to do so, all we are now doing is to spend a substantial but modest sum—hundreds of thousands of pounds rather than millions—first, for the design of the instruments, and secondly, for making the necessary designs for modifications of the American rocket, should it be decided when the time comes to use that vehicle Mr Macmillan said that he had asked the Lord President of the Council, in consultation with the Minister of Supply and other Ministers concerned, to exercise general supervision of these new developments

In repeating the Prime Minister's statement in the House of Lords on May 12, Lord Hailsham said that he had had very much in mind from the outset the correct deployment of our financial resources in different scientific spheres If he thought that what was now being done was in any way a rival to cancer research, or even that cancer research was being held up for purely financial reasons, he might take a different view He did not regard these two projects as rivals and thought that the merits of research projects should be examined in the light of hopeful leads and available personnel, rather than in terms of mere cash

That is clearly the right view to take and will be accepted by scientists generally The Prime Minister said there are two problems to be considered in relation to a British contribution to space research the nature and design of the instruments to be carried into space, and the vehicles in which these instruments are to be launched As to the first, with the assistance of Fellows of the Royal Society and with the endorsement of the Advisory Council on Scientific Policy, a programme for the design and construction of instruments to be carried in Earth satellites had been approved and work would begin at once

With regard to the second, Mr Macmillan said there might well be scope for joint action with the United States, with the Commonwealth or with other countries, and that a team of experts, including Prof H S W Massey, was being sent to Washington to discuss possible Anglo-American co-operation We are also opening consultations with other Commonwealth countries, and meanwhile design studies are being put in hand for the adaptation of British military rockets This would put us in a position, should we decide to do so, to make an all-British effort

On May 29 it was announced that Lord Hailsham had appointed a steering group on space research, under the chairmanship of Sir Edward Bullard This group—which includes Prof W V D Hodge, secretary of the Royal Society, Prof H S W Massey, Sir Harry Melville and the Astronomer Royal, and is subject to the responsibility of the Lord President of the Council, in consultation with the other Ministers concerned with the supervision of the Government's space research programme—"is to advise on the formulation of that programme and to co-ordinate the arrangements for its execution"

In replying to questions on his statement on May 12, the Prime Minister added that the instruments programme would be supervised by the British National Committee on Space Research set up by the Royal Society and under the chairmanship of Prof Massey He was certain that, in the field of scientific instruments, Britain should play her part in advancing the scientific effort In view of the importance of research in outer space he would probably use the appropriate moment at any 'Summit meeting' to discuss the desirability of a system of co-ordination and pooling of information with the Soviet Government The discussions with the United States were to be concerned with the possibility of some joint organization for the actual launching of the container for the instruments

In the House of Lords, Lord Hailsham dealt with this matter of international co-operation in replying to several supplementary questions Viscount Alexander of Hillsborough and Lord Rea urged the importance of keeping space research on an international basis as much as possible, and Lord Hailsham said that the Government has this aspect very much in mind He pointed out that both the Americans and the Russians, as well as ourselves, are co-operating in the Committee for Space Research, known as Cospar, a non-Governmental scientific body of the executive board of which Prof Massey is a member The United Nations Assembly last autumn set up an *ad hoc* committee to report to the next Assembly on the area of international co-operation in the peaceful uses of outer space which could appropriately be undertaken under United Nations auspices and the future organization of arrangements to facilitate such co-operation Great Britain and the United States, but not the U S S R, are co-operating with this Committee The Commonwealth as a whole is co-operating with both these international bodies and the Government is already inquiring of the Commonwealth countries what their contribution could be to the project announced by the Prime Minister

On this occasion Lord Rea urged the Government not to undertake too much, and Lord Hailsham's assurance that our scientific resources would not be dissipated was doubtless in response to this remark as well as to Lord Amwell's specific question about cancer research The trend of these developments, however, must have been known to Lord Hailsham when he spoke at the annual dinner of the Institution of Chemical Engineers on April 28, and his remarks on that occasion about the office of the Lord President of the Council are of the greatest interest in view of the wider responsibilities which the Lord President has now assumed and of which he was then presumably aware

Quoting Sir Hugh Beaver's remarks, Lord Hailsham agreed that the relation between government and science requires more attention than it is receiving and also that we are very far from arriving at the ideal solution—if, indeed, one exists—but he pointed out that the Lord President of the Council is not, and makes no claim to be, the head of British scientific thinking and planning Lord Hailsham did not think there could ever be any such person, but he naturally declined to speculate in public as to whether the Lord President has either the time or the means to discharge the duties laid upon him Such questions he obviously thought were worth asking and it could be taken that his remarks were designed to provoke discussion.

First, he questioned the wisdom of asking for "one coherent policy" on science, pointing out that science is not a subject but a whole thicket of subjects, some separate, some closely inter-related, but all animated by a common attitude of mind, and each contributing to a common corpus of knowledge Secondly, science cannot be abstracted from life, which it touches at every point If it is to play its part in industry or in government, it cannot be abstracted from them and then re-injected in a concentrated form Industries, including individual firms, need to be more scientifically minded, as do governments, including individual departments and ministers, but it would never be enough, however much time or means he had at his disposal, to have a single Minister responsible for the whole scientific field Such a Minister could never be a substitute for Ministers of Power, of Education, of Transport, etc, each of whom sought himself and through his staff to apply scientific techniques and knowledge to the problems of his office

For these reasons Lord Hailsham thought that what is wanted is not a new Minister or a new Ministry, but a new attitude on the part of the nation, the Government, industry and trade unions, in which each in his own sphere becomes more scientifically minded This, said Lord Hailsham, is "a continuation of the process which has been revolutionizing life on this planet for the past hundred and fifty years, and involves a more intelligent understanding of the forces at work To treat the problem thus as essentially one of education, Lord Hailsham admitted, will not answer any of the questions about the relation between Government and science, between education, research, industry and finance, or about the office of the Lord President, and he then discussed these relations more particularly

First, he emphasized that if the educational world and the scientific world are to perform their functions they must retain complete integrity and a high degree of independence This is essential even in the schools, and while the function of government in education is not easily defined, Lord Hailsham believed that the social value of an educational system depends on the curriculum remaining within the competence of the teaching profession As a matter of history, government entered the scientific sphere because no one else would do so on a sufficient scale, and this was now also true of education Nevertheless, Lord Hailsham urged that precisely because government plays, and undoubtedly would continue to play, a vital part as a patron of science, scientific decisions should be so far as possible in the hands of scientists Where it is practicable it is also desirable that they should draw on independent sources of finance, not in place of Government contributions but in addition to them Moreover, the direction of scientific policy should not be wholly in the hands of Government, but industry should be determined at every level to maintain its influence in its proper field of applied science and technical education, both by finance and by active participation both in its own and even in government-sponsored bodies, and this influence should be felt in the formation of policy and in the allocation of scientific man-power

Lord Hailsham's thesis is one that will commend itself to the scientist generally, and it is apparent from a paragraph in the last annual report of the Federation of British Industries that an important section of industry is prepared to undertake such responsibilities A detailed study of certain aspects of British research practice in relation to methods adopted abroad is already being made, so as to facilitate a detailed statement of industry's view of the Government's plans for industrial research as put forward by the Lord President's office Co-operation in technical education is also developing

Nevertheless, the thesis ignores the practical difficulty of deciding what is a scientific decision and what is a political decision Moreover, political decisions are liable to determine the resources available for scientific projects, both in terms of finance and of man-power This is well illustrated in the recent decision on space research It is the high cost of such research that is responsible for any concern with which the decision to enter that field may be regarded among scientists Great Britain has no margin for waste of scientific man-power or other resources, and it will be a prime concern of the Lord President and of Sir Edward Bullard and his steering group to see that Britain's limited effort is concentrated on the most profitable areas of research

Lord Hailsham showed clearly enough that he regards the Lord President of the Council as in some sense a Minister of research, though with the responsibility of a patron rather than of an overlord He pointed out that, measured by cost, most Government research is carried out under the Minister of Supply or by the Atomic Energy Authority, for which the Prime Minister is now directly responsible In the Civil Estimates for 1959–60, for example, expenditure on research and development is put, in round figures, at £270 million, of which £214 million is on the Ministry of Supply's vote, compared with £12 million for the Department of Scientific and Industrial Research, £3 5 million for the Medical Research Council and £4 5 million for the Agricultural Research Council This total, however, takes no account of whatever proportion of the £58 million for the universities which may be spent on research, or of the £92 million for the U K Atomic Energy Authority, which may go for research and development, though the estimates show that, of the last figure, £3 5 million is spent on research and development contracts with industry, the universities, etc

Even when it is remembered that the universities are still responsible for the larger part of Britain's effort in scientific research, these figures show that the Minister of Supply is too interested a party to be an entirely impartial adviser as to the expediency of a British space research programme Moreover he is also largely responsible for advising the Government as to the desirability of undertaking another costly long-term project—the development of a supersonic transport aircraft For the past two years a committee of leading aircraft designers and experts from the Royal Aircraft Establishment, Farnborough, has been studying the technical possibility of developing and building a supersonic air-liner, and if so, advising as to its optimum size, shape and speed

Lord Hailsham suggested that the present arrangement works satisfactorily although it may not be ideal Nevertheless, it should be noted that, in throwing on the Minister of Supply the responsibility for final recommendations in these matters, he is largely made judge in his own cause, and in one where the criteria are as essentially scientific as financial or economic It should also be remembered here that those who, like Prof A C B Lovell or Sir Harold Spencer Jones, have urged that Britain cannot afford to remain outside this new field of space research have done so on scientific grounds They are disturbed about the effect parsimony might have on our economic welfare and national well-being We depend indeed on our skill in manufacture, our ability to apply science and technology to the fullest possible extent, but we depend also on our ability to produce the new knowledge from which scientific and technical advance continually spring

Prof Lovell, in his Reith Lecture last year, specifically stressed benefits which mankind has reaped from fundamental scientific investigations carried out for their own sakes, and supported without thought of practical gain The programme of space research projected in the United States appears to comprise schemes for radiocommunication over great distances and for weather forecasting It also seeks to obtain data about the density and composition of the Earth's upper atmosphere, about the nature of interplanetary gas, the magnetic field of the Moon and the nature of the solid surface of Venus The tentative programme announced by the Prime Minister seems to offer scope for limited but worth-while experiments, and the ingenuity required to build the instruments for the satellites should be a valuable stimulus to the scientific instrument industry generally

If the programme is recognized as a reasonable compromise, the question of balance is nevertheless of great importance, and it has still to be shown that it will contribute anything essential to developing or extending the environment in which creative science flourishes We cannot argue that the project will help to retain promising scientists in Britain, without inquiring whether the prospects and opportunities in other scientific and technical fields are sufficiently attractive to keep them here This means something more than the assessment of priorities, or consideration of whether the Government is sufficiently alive to its responsibilities in other fields of research where considerations of high cost have, as Lord Hailsham admitted, made its entry imperative Biology and medicine have been specifically mentioned by critics of the present proposal, and in spite of what was said of cancer research in the House of Lords, progress in both these fields is regarded by some as gravely hampered by lack of funds

It is in this context that the whole organization of research in Britain is important, and independently of the merits of the space research programme, fuller investigation is undoubtedly needed into the returns that can be expected from investment in research in particular fields It may well be asked, as a question of economic survival, whether we can afford to spend about ten times as much on defence research as on pure and applied research generally, and whether everything possible is being done to avoid duplication of effort or waste of resources

The criticisms which were made by Mr Stanley Mayne, general secretary of the Institution of Professional Civil Servants, at the Institution's annual conference at Folkestone on May 25 may seem to refer to comparatively minor points, but nevertheless they indicate that the organization of research needs a little more consideration than Lord Hailsham was inclined to admit Mr Mayne welcomed the decision on space research and the 70 per cent increase in the expenditure of the Department of Scientific and Industrial Research, but was highly critical of certain decisions taken by the Council for Scientific and Industrial Research, particularly its failure to consult the directors of research laboratories in reaching major decisions concerning the future of those laboratories Mr Mayne asserted that there had also been no consultation with the advisory bodies of scientists associated with these laboratories, and pointed out that such failures in consultation or co-operation are liable to engender a spirit of frustration among the scientists concerned, whether they are on the staff of the laboratories or on the advisory bodies He also said that frustration is developing in the atomic energy research organization through a similar failure to consult with the staff or to explain the purpose of changes in organization

Mr Mayne's charges are essentially of bad management rather than of mistaken policy, and it is, of course, true that weakness in administration can be fatal in recruiting staff of high ability and enthusiasm Such defects, however, do not necessarily arise out of the structure of research organization unless it is seriously overloaded, but these criticisms lend some support to the suggestion put forward in the May issue of the Institution's journal, *State Service*, that the powers of the Lord President of the Council should be extended and that he should give more or less full time to his scientific responsibilities Lord Hailsham's speech to the Institution of Chemical Engineers seems to imply that this would be more in line with his own thinking than the creation of a Ministry of Science The further suggestion that consultation between individuals and bodies concerned with science should be improved also seems to agree with his views

Lord Hailsham might have reservations as to how far it is possible to frame precise recommendations as to the proportion of national resources which should be devoted to the training of scientists, scientific research and the application of scientific knowledge and the results of research to the national welfare, but he is undoubtedly concerned to stimulate co-operation and consultation and, above all, constructive thought as to how the scientific effort of Britain should be organized and what range of problems it is desirable to investigate It should be noted that he referred specifically to the contribution which professional bodies such as the Institution of Chemical Engineers could make to the formulation of policy and to the dependence of progress in technology on partnership between government, teaching bodies, research scientists and industry The value of such co-operation was stressed, from a different point of view, by Dr P F R Venables, principal of the College of Technology, Birmingham, and by Mr J J Gracie, chairman of the Governing Body, at the associateship presentation ceremony on April 25, both of whom referred to its importance in recruiting first-class teachers for the colleges of technology and in maintaining the conditions of service, including research, which would attract such men and women Lord Hailsham's address should stimulate both the constructive thinking and the close co-operation in all such matters which the launching of a British space research programme makes even more imperative, as it does also the need to consider our research effort as a whole and to keep it in balance with the man-power resources and varied needs of the nation

ORIGINS AND METHODS OF THE SCIENCES

Studies in the History and Methods of the Sciences By Arthur David Ritchie (Edinburgh University Publications History, Philosophy and Economics, 2) Pp vi+230 (Edinburgh The University Press, 1958 Distributed by Thomas Nelson and Sons, Ltd , 1958) 12*s* 6*d* net

FEW professional philosophers can have had Prof A D Ritchie's long, intimate and diverse acquaintance with science or rather, as he would rightly insist, with the sciences, since (in his words) "singular SCIENCE is the Sacred Cow of twentieth century idolatry" Chemistry and philosophy at St Andrews were followed by the Natural Sciences Tripos at Cambridge, then by four years as chemist with the Naval Airship Service during the First World War Next came two years' return to philosophy, then seventeen years in physiology and biochemistry in the Medical School at Manchester, before he turned whole-time to philosophy Perhaps when he retires from the chair of logic and metaphysics in the University of Edinburgh he will find occasion now and then to turn back to his early love of marine biology and comparative physiology In any event, he is singularly well qualified to write such a book as this his scientific friends will welcome the product of his multiple interests and critical thought

But others, too, will read it with appreciation, sympathy and attention for Ritchie's long concern with the sciences, their methods and their philosophy, is coloured by a broad humanity, and by a deep reverence which shows itself in a frankly religious approach to ultimate problems Lest such reverence be misunderstood, misunderstanding, as he writes, "has nearly always come of supposing that there are sacred *things*, whereas we know directly only of sacred *relations*" But Ritchie's humanity and reverence do not lead him to compromise with nonsense Marxists will not like this book, nor those infected with "the common error of supposing that physics is the one and only science", nor any biologists whose attitude is rooted still in the simplicities of nineteenth century physics

But to many others it will give much pleasure and enlightenment, particularly to those, like the present reviewer, who are sadly ignorant of the origin, history and philosophy of the sciences—if not of their methods, and to any who do not believe too piously that the secretions of the Sacred Cow can cure at once all human maladies, it will bring frequent and wholesome laughter It covers in a remarkably short space the origin of geometry, astronomy, chemistry via alchemy, biology in many aspects, 'human order' and cosmologies and it leaves no doubt of its author's conclusion that all these sciences, including mathematics, were derived originally from observation and experience, from the practical arts That does not mean, as he insists, that an even greater part in their development was not played by intellectual curiosity, by bold and critical thought, by trying to find order amid disorder but the order to be found was among real things, thrown up by measurement, by construction, by working metals, by observing the sky and the seasons, by breeding plants and animals and by medicine

The natural sciences to-day, and the technologies based on them, are taking an ever-growing part in human affairs, and apart from major disaster the growth will certainly continue But unless the process is critically watched and wisely guided a sort of chain reaction might set in, which could end in science and technology taking charge and leading man—who knows where ? It is vitally important, therefore, that thoughtful people of every kind should know something of the origins, the methods and the motives of the sciences, that in fact an enlightened public opinion should be formed the intelligent and humane cannot hope to guide if they do not understand at all So a world of good might be done if this book were widely read and discussed A V Hill

SCIENCE AND LITERATURE

The Scientific Background

A Prose Anthology By Prof A. Norman Jeffares and M Bryn Davies Pp xii+306 (London Sir Isaac Pitman and Sons, Ltd , 1958) 21*s* net

THE purpose of this book is two-fold to demonstrate to science students the precision and lucidity of the best scientific writing, and to offer to arts students and to the general reader a pleasant means of entry into the world of science The authors have fulfilled their first aim but have left the second in doubt Certainly the book is pleasant enough and should take its place as one of the most useful of recent bed-side books The intention of the authors is admirable, necessary and timely They point out the difficulties of the communication of scientific discoveries and ideas both because of the development of terminologies and professional jargon and the general deterioration in the ability to use language as a precise instrument The authors show that good scientific prose is good English prose and certainly give pointers towards a closing of the gap between science and arts

There are several ways of regarding the "background of science" The phrase has been used to describe the philosophy, the methodology, the sociological implications and the history of science The authors have chosen the literary background, but it still remains true that a great deal of communication in science remains mathematical and diagrammatic , thus, the fundamentally important problem of the semantics of communication theory in science is not explored

Within the limits of the pages at their disposal the authors have dealt with a part of the problem Those who expect a documentary history of science or even a series of readings in chronological order will be disappointed

The introduction is brilliantly written it should be read and learnt by every student of arts and science and everyone who is interested in education "The most pressing educational problem of the moment is how to remedy the broad divergence brought about by specialization between the two main branches of knowledge, the sciences and the humanities"

The substance of the book consists of a hundred short extracts of diverse types and purposes The first half dozen on writing are of great value Thereafter, there is an intriguing mixture The Krakatoa sunsets by the poet Gerard Manley Hopkins rubs shoulders with "Mathematics and Beauty" by C A Coulson Among extracts from the literature of the more common grammar school and university sciences we find "How to Climb the Turret of King's College Chapel, Cambridge" , Hoyle v Dingle and Dingle v Hoyle , James Kirkup's poem "A Correct Compassion" on a heart operation All these make an interesting *mélange* Some of the passages are too short and scrappy to have more than a sampling value Since the language of science cannot be divorced from its aims and methods, some longer passages, on the lines of Sir Cecil Dampier's "Cambridge Readings in the History of Science", would be useful

Sir Isaac Newton on the Law of Gravitation requires more than a page, and Faraday's wonderfully lucid "Chemical History of a Candle" demands a long extract, otherwise we do not see enough of the canvas on which he paints to obtain any idea of the whole picture

The book concludes with a number of questions which relate to each of the passages These should provide a useful basis for further analysis and discussion W L Sumner

TOXÆMIA AFTER BURNING

L'Auto-Intoxication après Brûlure

Par R Godfraind Pp 191 (Bruxelles Editions Arscia S A , 1958) n p

THE general effects of extensive burning are so profound and complex that it is not surprising that an all-embracing concept of toxæmia or auto-intoxication was put forward many years ago The idea, which apparently originated from Avdakoff in 1876 in St Petersburg, implied that toxin(s) formed in the skin after burning are absorbed into the circulation and may produce illness and death , but the number and variety of the 'toxins' which have been reported over the years in the blood, urine or burned skin are legion and indicate its elusive nature The hypothesis at one time led to the treatment of burns by tanning, which was said to precipitate the altered skin proteins and prevent absorption of their degradation products , but the tannic acid form of treatment itself produced 'toxic' effects and tanning is now discredited The concept of toxæmia has lost ground, first, through increasing knowledge of the hæmodynamic nature of burn 'shock', oligæmia and its relationship to the inflammatory exudation into the burned area , and secondly, through the recognition of the importance of bacterial infection of the burned surface and subsequent bacterial invasion of the body which can certainly produce the clinical picture of toxæmia Nevertheless, a number of important observations on burns remain unexplained, including the experimental observation reported originally by Wilson and his colleagues in Edinburgh that the œdema fluid from the burned skin of rabbits developed lethal properties for other rabbits and mice This aspect of toxæmia has been experimentally pursued by Simonart and Godfraind in Louvain Dr Godfraind's monograph is an account of their work on the role of proteins and their degradation products in burn toxæmia

The first part is concerned with the toxicity to frogs of heated fibrinogen and serum albumen, their peptic and plasmin hydrolytic products and with the composition of the œdema fluid in burned frogs The theme is developed in the second part of the book, which is concerned with studies in the rabbit on the toxicity of peptides, particularly when given subcutaneously, and an account of the pathology produced , with the œdema provoked by injection of peptides and its comparison with burn œdema fluid The toxicity of burn œdema fluid for other animals is confirmed, and this is related to protein fractions, particularly the euglobulin part of the exudate The whole process is said to be triggered-off by the activity of skin and other proteases after burning which, by the splitting of tissue and other proteins to polypeptides, induce local œdema , the exudation of plasma proteins follows, some of which become altered and are toxic on absorption

The author tries to account for the renal, gastro-intestinal, adrenal and other changes after burning on the basis of a peptide-induced toxæmia, but the argument is weak He greatly underestimates the parts played by oligæmia in producing the acute illness of burns, and also of bacterial infection and septicæmia The monograph contains useful material on the biological properties of proteins and their split-products, much of which is relevant to the recent work of Miles, Wilhelm, Spector and their colleagues in Britain on the role of blood proteins and polypeptides in the pathogenesis of acute inflammation The book is well produced , it has a summary in English and regard is paid to the work of others, including British workers

S SEVITT

DIFFERENTIAL EQUATIONS FOR INSTRUMENTATION ENGINEERS

Ordinary Differential Equations

By Dr Wilfred Kaplan (Addison-Wesley Series in Systems Engineering) Pp xv+534 (Reading, Mass Addison-Wesley Publishing Company, Inc , 1958) 8 50 dollars

THIS book can be used as a standard text-book on differential equations, for it covers much the same ground as, for example, Piaggio's well-known work , but it is intended particularly for students of instrumentation engineering, so that applications to servo-mechanisms, computers and controls are emphasized, and technical terminology is frequently employed Thus for the linear equation $F(D)\,x = f(t)$, the function $f(t)$ is termed the input, and if the complementary function (the solution for zero input) tends to zero with the time, the equation is said to be stable, the complementary function is a transient, and the complete solution is effectively represented by a particular integral, termed the output This phraseology is probably more graphic and so more easily appreciated by the student of control engineering than the familiar but flat language of the pure mathematician It also emphasizes the role of the differential equation as a functional transform from input to output, and so links up with the modern transform calculus The author keeps well in view the idea that the proper question to ask about a differential equation is not whether it can be solved but how much does it tell us about the function which satisfies it

Existence theorems are not ignored, but are placed at the end of the book and so need not obstruct a first reading Much of the material is classical and need not be specified here, but for more recent work there is a good section on matrices and their connexion with linear differential equations, and a most helpful introduction to the phase-plane method for non-linear equations The student who is daunted by the concentrated stimulus of Lefschetz or the high abstract precision of Coddington and Levinson might do well to play himself in through these chapters in Kaplan's book

In a book of 500 pages, to devote only 14 to numerical methods is derisory , there should be either a great deal more, or nothing save the half-page of references Simultaneous linear equations with constant coefficients occupy much space, but the methods given seem to be generally more awkward than Routh's efficient procedure There is nothing about modern operational or transform methods, save two or three pages on the application of the Laplace transform to constant-coefficient linear equations, too sketchy to be of value either to the ignorant or to the informed But this omission is fully explained by the author's promise of a speedy appearance of his companion volume on operational methods for linear systems

T A A BROADBENT

FERROELECTRICITY

Ferroelectricity in Crystals

By Helen D Megaw Pp xi+220 (London Methuen and Co , Ltd , 1957) 27*s* 6*d* net

FERROELECTRICITY is a subject of relatively recent origin, which is, at the moment, developing with exceptional rapidity The number and range of original papers are a constant strain on the time of investigators in the field, and must be bewildering to beginners These circumstances call for a skilful review of the subject, and this has been admirably accomplished by Dr Megaw in "Ferroelectricity in Crystals" This is a short book (only 220 pages), but by careful selection, logical arrangement, and lucid exposition the author has produced a volume which can be both a 'source book' to the expert and an introduction to the beginner

The first chapter gives a brief outline of the subject, with clear definitions of the new terms involved The following six chapters summarize the experimental data on Rochelle salt, potassium dihydrogen phosphate, barium titanate, other perovskite materials, and miscellaneous structures such as cadmium niobate and guanidine aluminium sulphate hexahydrate The remaining three chapters expound the present theoretical position, including the thermodynamic method of correlating observed properties, and the basic features of current theoretical models of ferroelectrics

The approach to the problem is essentially crystallographic, and the object of bringing out the close correlation between the structure, and the intrinsic electric properties of the single domain is successfully achieved The treatment gains in clarity by making only brief reference to domain dynamics, with its murky problems of failing memories and fictitious surface layers

The book has a short, well-chosen index, and a most useful glossary of crystallographic terms There are copious references to original papers throughout the text, which are listed at the end of each chapter

Altogether this is a book of exceptional merit, and it is only to be hoped that demand proves sufficient to allow further editions to be produced at not too long intervals

L E CROSS

ROLE OF THE SCHOLAR IN SOCIETY*

By Dr HENRY ALLEN MOE

Secretary-General of the John Simon Guggenheim Memorial Foundation, President of the American Philosophical Society

RALPH WALDO EMERSON, who made it, declared that a scholar's first duty in society is not to quit his belief that a popgun is a popgun, although the ancient and honourable of the Earth affirm it to be the crack of doom. It is all there, all that anyone needs to know about the function of the scholar in society in these days, or in any days: you go where your evidence takes you; and there you stand, even though the ancient and honourable of the Earth are sure that you should be standing somewhere else.

But in this modern world—the world in which the Newtonian mechanics, to cite but one example, have been shown to have less than the divinity which hedged them about for centuries—I conceive that the Emersonian declaration needs a Moeian rescension: "Neither shall the scholar quit his belief that the crack of doom is the crack of doom, although the ancient and honourable of the Earth affirm it to be a popgun."

Of the need for this rescension, there are many examples; and in view of the fact that this is the centenary of the publication of Charles Darwin's "On the Origin of Species", I shall refer first to that crack of doom for much of theology and more of biology. The first edition of that book, all 1,200 copies, was sold out, it is true, in less than a day; but then the wielders of the popguns began to pop.

An article in *The Quarterly Review* said that Darwin was attempting in his book "to prop up his utterly rotten fabric of guess and speculation" and declared that it was all "utterly dishonourable to science". *The Spectator* accused Darwin of collecting a mass of facts to substantiate a false principle. Darwin's own college, Trinity at Cambridge, would not permit a copy of the "Origin" in its library. Sir John Herschel, the astronomer, described Darwinism as "the law of higgeldy-piggeldy". Darwin's old geology professor at Cambridge, Sedgwick, wrote to Darwin that the book was "false and mischievous" and added that when he read it had "laughed till his sides ached".

But there were defenders, too: T. H. Huxley, Charles Lyell, geologist, Asa Gray, American botanist, the last-named contradicting his colleague Agassiz at Harvard. The end of the pros and cons is not yet in sight; but, undoubtedly, it was not a popgun that Darwin fired off, although many of the ancient and honourable of the Earth were strongly of that opinion.

Moreover, there was Dante of the thirteenth and fourteenth centuries, in some ways the greatest mind of all time, who, as Oliver Goldsmith put it clearly and accurately, "first followed Nature and was persecuted by his critics as long as he lived"—in and out of exile and in and out of prison. Sick with petty quarrels and dissensions, Dante strained the eyes of his mind toward the hills, for the appearance of a universal monarch who should be raised above the flaws of faction and the spur of political ambition, under whom each country, each city, might (under the institutions best suited to it) lead the life and do the work for which it was best fitted. United in spiritual harmony, Dante showed to the world for the first time a plan of a government where the strongest force and the highest wisdom were interpenetrated by all that God had given to the world of piety and justice; and it is not possible to say that Dante's dream did not work its own realization nor to deny that the high ideal of the poet had its effect. For, five centuries later, it became embodied in the constitution of the Italian State, which still has no stronger bond of union than a common worship of the exiled and imprisoned poet's indignant and impassioned verse[1].

But I need not multiply my examples: everyone will have those that are better and clearer for himself, because they flow from his own fields of interest. Nevertheless, for me there still remains to relate the poignant example of Edward FitzGerald's translation—which is more than a translation—of "The Rubaiyát of Omar Khayyám". The centenary of its publication has been scarcely observed. It appeared in April 1859 for sale at 1*s*. a copy. But it found not one buyer at that price; and all 250 copies of the first edition were remaindered at 1*d*. each.

Omar, a son of the tentmaker, was, in his lifetime, famous as philosopher, astronomer and mathematician. He was one of the eight astronomers appointed by the eleventh-century Persian Malik Shah to reform the calendar; and as FitzGerald has him say in his verses (for 'Rubáiyát' simply means verses):

> "Ah, but my Computations, People say
> Reduced the Year to better reckoning? Nay,
> 'Twas only striking from the Calendar
> Unborn Tomorrow and dead Yesterday."

Omar's contemporaries honoured him for his mathematical and astronomical computations; but, for his verses, they denounced him as a free-thinker. The "Rubáiyát", in essence, is a plea for tolerance: in it, everything is tolerated except intolerance. This point of view was offensive to orthodox Muslims. As was said in "The Book of Learned Men", an Arabic biographical work of the thirteenth century: "The inner meanings [of Omar's verses] are as stinging serpents to the Musselman law; hence, the men of his day hated him. . . ."

Being disapproved in contemporary eleventh-century Islam, the verses lay in obscurity on through the ages. So small was their interest that only two manuscripts have been found—one in the Bodleian Library of the University of Oxford, and one in the Library of the Asiatic Society of Bengal in Calcutta.

The resistances which the eleventh-century Omar's verses met in Islam were no different in kind from the resistances which the FitzGerald translation met in nineteenth-century Christendom So it was that Edward Cowell, the Persian scholar who had introduced FitzGerald to the "Rubáiyát" manuscripts, wrote that he would not permit a book on the Omar verses to be dedicated to him "I unwittingly incurred", he said, "a grave responsibility when I introduced his poems to my old friend I admire Omar but I cannot take him as a guide"[2]

---

* Substance of an address delivered on May 21 at the Rockefeller Institute Convocation for Conferring of Degrees and Dedication of New Buildings (see also *Nature* of June 13, 20 and 27, 1959).

In the pre-Darwinian Western world, when all things were known or could be known by revelation —especially about human affairs—words such as these by Omar had no takers

> "There was the Door to which I found no Key ,
> There was a Veil through which I might not see "

But Omar had seen clearly that the great questions always stand—*all* the great questions of literature and history and philosophy and science stand—outside the limits of finality It is a lesson we have not learned to this day To cite an example, from a field in which many of you must tread more familiarly than I—an example which I have from that very great mathematician, Hermann Weyl—as late as 1923 the writers on relativity theory and tensor calculus were accused by some of the ancient and honourable of the Earth of having laid waste a rich cultural domain, that rich cultural domain being the algebraic theory of invariants This time, what was called a popgun truly became the crack of doom

But a new key, which the ancient and honourable of the Earth had not found, was found in the theory of representations of continuous Lie groups , and by these new means the old problems which, according to the complaint, the relativists had let go by the board have been attacked on a much deeper level than was possible by the algebraic theory of invariants[3]

There still is a "Veil through which I might not see", still a "Door to which I found no Key" , but the Veil and the Door are different veils and different doors, placed further down the corridor of men's eternal quest for Truth

> "Of all sad words of tongue or pen" [wrote our
> own Whittier],
> "The saddest are these, it might have been"

One is tempted to wonder, in the most futile of wonderment, as I know, what might have happened in Islam as well as in Christendom, in the Middle East as well as in the West, if the freedom-giving intellection behind Omar Khayyam's "Rubáiyát" had become as well understood as Charles Darwin's intellection "On the Origin of Species"

But let me not engage in speculative futility on this occasion Rather, let me hope with Omar, for each one of us, that

> "Of my base metal may be filed a Key
> That shall unlock the Door he [the Dervish] howls
> without"

"A Hair, perhaps, divides the False and True", wrote Omar in the eleventh century A hair, perhaps, divides the popgun from the crack of doom, the crack of doom from the popgun The function of the scholar in any society is to make that division for himself and then to stand on the side of the divide that represents truth for him

LYMAN-ALPHA PHOTOGRAPHS OF THE SUN

By J D PURCELL, DR D M PACKER and DR R TOUSEY
U S Naval Research Laboratory, Washington 25, D C

SPECTRA photographed from rockets by the University of Colorado[1,2] and by the U S Naval Research Laboratory[3] have shown that the Lyman-alpha line of hydrogen, λ1215 7A , is emitted by the Sun with high intensity Little beyond this is definitely established concerning the details of the emission Values of half-width vary between 1 A , reported by Miller *et al* [2], and not more than 0 3 A , published by Johnson *et al* [3] The total intensity of Lyman-alpha during the recent years near the sunspot maximum has been found by Byram *et al* [4] to be 5–6 ergs/cm ^{2} sec , on a number of rocket flights Whether the much lower values recorded earlier near sunspot minimum were correct is controversial

The first Lyman-alpha photographs of the solar disk were obtained by Mercure *et al* [5] in 1956 Each of the four images obtained showed three regions where the density was approximately 0 03 greater than the scattered white-light background This blackening was attributed to Lyman-alpha radiation and was found to agree, approximately, in position with the three principal areas where plages were located in calcium *K* and hydrogen-alpha spectroheliograms Low resolution and prominent grain made further correlations impossible, and the limb of the Sun was not sharply defined

A new series of Lyman-alpha images of the Sun was obtained from an *Aerobee-Hi* rocket between 15 47 5 and 15 48 5 U T on March 13, 1959 The altitude ranged from 110 to 170 km , which was sufficiently high to be above appreciable atmospheric absorption at this wave-length Simultaneously, the Sun was photographed in white light, hydrogen-alpha and calcium *K* The Mount Wilson, McMath-Hulbert and Sacramento Peak Observatories, the Naval Observatory and the Naval Research Laboratory co-operated in this programme

Fig 1 shows a diagram of the instrument, described by Purcell[6] It is essentially a double monochromator, using two 40-cm radius gratings with 600 lines per mm in the first order, arranged so that the dispersions are additive The Lyman-alpha image of the Sun formed by the first grating is passed by an aperture in a diaphragm which intercepts the rest of the spectrum The second grating disperses the light again, forming a Lyman-alpha image enlarged by a factor of 2 and freed from stray light The first grating was mechanically deformed, as described by

Purcell and Tousey[7] in such a way as to produce a stigmatic image. One grating was coated with aluminium plus magnesium fluoride, the other with zinc sulphide, with specular reflectances at λ1216 A. of 80 per cent and 31 per cent, respectively, as described by Hass and Tousey[8]. As a result, the system was very fast and 1/50 sec. was sufficient to produce a good image. The entire unit was kept pointed at the Sun with a servo system constructed by the University of Colorado.

In Fig. 2 is reproduced one of the 1/50 sec. Lyman-alpha solar disk images. Presented for comparison are a calcium $K_{2,3,2}$ spectroheliogram obtained by the McMath–Hulbert Observatory, and a hydrogen-alpha$_{2,3,2}$ image photographed by the U.S. Naval Research Laboratory. Both were made while the rocket was in flight. The white-light photograph was made by the U.S. Naval Observatory at 13.57 U.T., on the same day. The axis of the Sun is vertical with north at the top and east at the right.

SUN

Fig. 1 Optical diagram of the Lyman-alpha camera

It is apparent that Lyman-alpha radiation is emitted most strongly from plages, and that the pattern of emission resembles calcium *K* more than

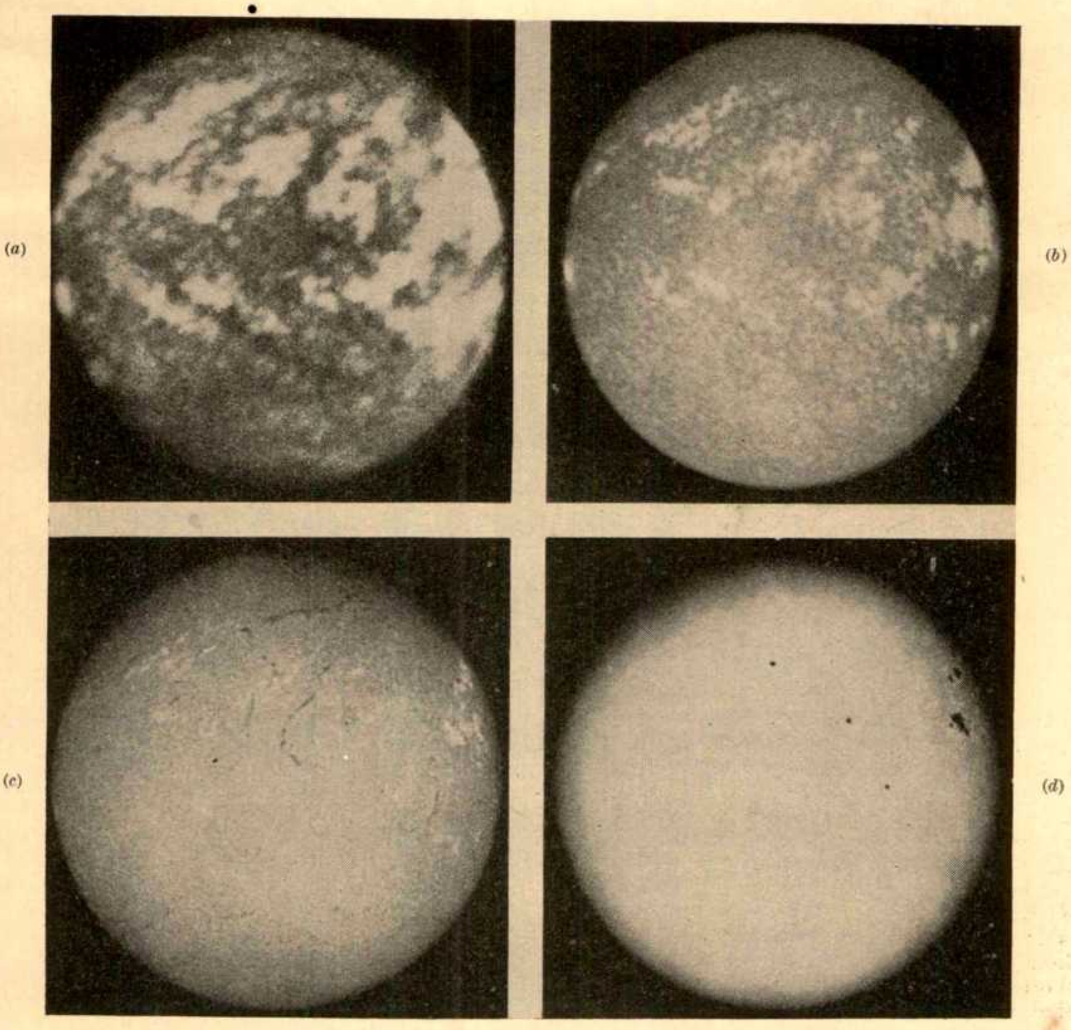

Fig. 2. Images of the Sun on March 13, 1959. (*a*) Lyman-alpha of hydrogen from *Aerobee-Hi* rocket; (*b*) calcium $K_{2,3,2}$ spectroheliogram (McMath–Hulbert Observatory); (*c*) hydrogen-alpha with 0·7 A. monochromatic filter (Naval Research Laboratory); (*d*) white light (U.S. Naval Observatory)

it does hydrogen-alpha radiation. The Lyman-alpha image differs from calcium *K* by having a larger ratio of intensity between bright and dark features, and by having a coarser structure.

The solar Lyman-alpha image in general shows detail down to about 1 min. of arc only; it is probable that this limit was set by the resolving power of the instrument. However, there is reason for believing that the coarseness of the pattern may, in part, be a real characteristic of the Lyman-alpha image, because the instrumental resolving power was found to be 1/3 min. in the laboratory, and because some details down to half a minute of arc appear in the solar image. The very fine stippling is, of course, photographic grain.

The correlation between features in the calcium *K* and Lyman-alpha images is striking. If the detail in the calcium *K* image is reduced to about the same as that present in the Lyman-alpha image, which can be accomplished by viewing the print out of focus, all the bright details in the two images match approximately.

The high contrast between Lyman-alpha plages and the background is quite noticeable. From preliminary measurements it appears that the ratio between the intensity of the brightest plage and the average inactive region is twice as great as in the corresponding regions of the calcium *K* image[9]. As a result, the Lyman-alpha plages seem to cover a larger fraction of the disk than the calcium *K* plages (observations furnished by courtesy of McMath–Hulbert Observatory). However, if the faintest calcium *K* plages are included, the difference in area covered is not great.

Conspicuous in the Lyman-alpha image are several broad dark lines. One follows the course of the calcium *K* filament in high northern latitudes. The most prominent dark line lies below the equator, at an angle of about 30° to it. This can barely be seen in the calcium *K* and hydrogen-alpha images. There is no corresponding well-defined filament in hydrogen-alpha and only a trace of a filament in calcium *K*. Such an outstanding feature cannot be attributed to a narrow filament alone, since a sharply defined narrow filament, when photographed at low resolution, would form a broad but extremely faint dark line.

The darkest part of the Lyman-alpha image is near the centre of the Sun. Limb darkening or brightening, in general, would be difficult to establish because of the complicated and varied pattern over the disk.

Most of the sunspots, shown by white light, do not appear in the Lyman-alpha image. The large group near the limb cannot be seen at all. The centre of the string of three, which is surrounded by a penumbra in the *K*-line image, is visible as a large hole in the corresponding Lyman-alpha plage. The upper of the three can also be seen.

The limb, as shown in Fig. 2, is clear-cut and real. In several of the long Lyman-alpha exposures, which are not reproduced here, prominences can be seen. The correlation with hydrogen-alpha prominences is good. The largest prominence seen in the Lyman-alpha radiation can be followed out to about 1 min. of arc from the limb, which is about the same as for the hydrogen-alpha image.

The high intensity and great extent of the Lyman-alpha plages suggest that the total intensity of Lyman-alpha radiation emitted by the Sun might be expected to depend on the extent of the plages. The total area covered by intense calcium plages reaches a maximum at sunspot maximum, and falls off to near zero at minimum. If the Lyman-alpha plages behave in a similar fashion, the Lyman-alpha emission intensity of the Sun should vary significantly between sunspot maximum and minimum.

CONVERSION OF LIGHT INTO CHEMICAL ENERGY IN PHOTOSYNTHESIS

By PROF. DANIEL I. ARNON

Laboratory of Plant Physiology, University of California, Berkeley

THE discovery[1-3] in 1954 that isolated chloroplasts are capable of forming carbohydrates from carbon dioxide and water with a simultaneous evolution of oxygen, with no energy supply except visible light, has opened a way for investigating the central problem of photosynthesis, the conversion of light into chemical energy, in a physiologically viable system free from the structural and functional complexity of the whole cell. This approach has already forced a re-examination[4] of certain established concepts in photosynthesis. One of the most fruitful of these concepts in guiding contemporary research in photosynthesis, including the current work with isolated chloroplasts, has been the theory of van Niel[5] that photolysis of water is the basic reaction, common to green plants and photosynthetic bacteria, for converting light into chemical energy. However, very recent experiments[6-9] with isolated chloroplasts and cell-free particles of the photosynthetic sulphur bacterium, *Chromatium*, now suggest that photosynthetic phosphorylation rather than photolysis of water is the common denominator of photosynthesis in bacteria and in green plants. The purpose of this article is to trace the recent evolution of this alternative view of photochemical events in photosynthesis, and to present, in a unified fashion, some of the evidence and considerations on which it rests.

Separation of Light and Dark Phases of Photosynthesis in Green Plants

It has long been considered (literature cited in ref. 10) that carbon assimilation proper is a dark, chemosynthetic phase of photosynthesis, and that the reactions involved are, in all probability, not peculiar to photosynthesis but rather reversals of those responsible for the degradation of sugars in respiration[11] Support for this point of view is found in the recent identification by Trudinger[12] and Aubert *et al* [13] in the chemo-autotrophic, but non-photosynthetic, bacterium *Thiobacillus denitrificans*, of the same cyclic mechanism for carbon dioxide assimilation in the dark as is found in photosynthesis of green plants[14] Moreover, Racker[15,16] has recently obtained, in the dark, a synthesis of hexose phosphate from carbon dioxide by a multi-enzyme system consisting of glycolytic enzymes from rabbit muscle and yeast and the pentose cycle enzymes from spinach leaves In his experiments, the energy needed for this synthesis was supplied by including in the reaction mixture exogenous adenosine triphosphate and an enzymatic device for generating, in the dark, reduced diphosphopyridine nucleotide at the expense of added molecular hydrogen or alcohol

If the experiments of Racker are taken as a model for the dark carbon dioxide assimilation in photosynthesis by green plants. as was proposed by Calvin[14], then the essence of photosynthesis, the conversion of light energy into physiologically useful chemical energy, must lie in the photochemical reactions which generate adenosine triphosphate and reduced pyridine nucleotides at the expense of absorbed light energy Moreover, since the dark reactions responsible for carbon dioxide assimilation do not result in oxygen evolution—which remains a unique characteristic of photosynthesis in green plants—the photochemical phase of photosynthesis must account for the formation of three products oxygen. reduced pyridine nucleotide and adenosine triphosphate

In the intact cell, the conversion of light into chemical energy is closely bound with carbon dioxide assimilation, the light and dark phases of photosynthesis are closely interwoven, and attempts to separate them experimentally have so far yielded no effective method for investigating the mechanism of the photochemical reactions Thus, when whole cells were pre-illuminated in the absence of carbon dioxide they were shown to acquire in light only a short-lived capacity, measured in seconds[17] or minutes[18,19], for a subsequent dark carbon dioxide fixation There was no agreement as to the chemical nature of this transient and unidentified product of the light reaction Calvin *et al* [19] characterized it as a "reducing power" whereas Gaffron *et al* [17] considered it to be an acceptor substance for carbon dioxide fixation Likewise, with respect to adenosine triphosphate, experiments with whole cells have given no clue as to the mechanism and site of adenosine triphosphate formation in photosynthesis In general schemes for photosynthesis, adenosine triphosphate required for carbohydrate synthesis was usually assumed to come from oxidative phosphorylation by mitochondria (see, for example, ref 20 (Fig 7), and also review, ref 21)

A special contribution of experiments with isolated chloroplasts to the study of the mechanism of photosynthesis is that they have provided an effective experimental approach to the separation of the light-dependent phase of that process, in which oxygen, reduced triphosphopyridine nucleotide and adenosine triphosphate are formed, and the dark phase during which carbon dioxide is assimilated A physical separation of the two phases of photosynthesis by fractionating chloroplasts has recently been described by Trebst *et al* [10] The light phase was completed first by the complete chloroplast system in the absence of carbon dioxide and resulted in an evolution of oxygen accompanied by an accumulation of reduced triphosphopyridine nucleotide and adenosine triphosphate in the reaction mixture The green portion of the chloroplasts (grana) was then discarded, and when carbon dioxide was next supplied to the remaining non-green portion of the chloroplasts (stroma) in the dark, it was assimilated to sugar phosphates The two phases, when carried out separately, yielded, essentially, the same final photosynthetic products as the continuously illuminated chloroplast system The conclusion seemed justified, therefore, that the conversion of absorbed light energy into the chemical energy used for carbon dioxide assimilation in the dark occurs during the photochemical reactions in which chloroplasts evolve oxygen and form assimilatory power[4], that is, adenosine triphosphate and reduced triphosphopyridine nucleotide These two substances are then, so far as it is now known, the first stable chemical compounds formed by green plants at the expense of absorbed light energy and are thus the true 'first products of photosynthesis', a term which has usually been applied to products of carbon dioxide fixation, such as phosphoglyeracte[14]

Photochemical Reactions in Cell-free Systems

The three products of the light reactions in chloroplasts, oxygen, adenosine triphosphate and reduced triphosphopyridine nucleotide, are now known[4,22] to be formed by two reactions*

$$\mathrm{ADP} + \mathrm{H_3PO_4} \longrightarrow \mathrm{ATP} \qquad (1)$$

$$\mathrm{2TPN} + \mathrm{2H_2O} + \mathrm{2ADP} + \mathrm{2H_3PO_4} \xrightarrow{\text{reductase}} \mathrm{2TPNH_2} + \mathrm{O_2} + \mathrm{2ATP} \qquad (2)$$

A non-physiological variant of reaction 2 is reaction 3, in which triphosphopyridine nucleotide is replaced by ferricyanide (represented here by Fe^{3+})

$$\mathrm{4Fe^{3+}} + \mathrm{2H_2O} + \mathrm{2ADP} + \mathrm{2H_3PO_4} \longrightarrow \mathrm{Fe^{2+}} + \mathrm{O_2} + \mathrm{2ATP} + \mathrm{4H^+} \qquad (3)$$

Reactions 1 and 2 revealed a previously unknown capacity of chloroplasts to use light energy for the formation of the energy-rich pyrophosphate bonds of adenosine triphosphate, a process called photosynthetic phosphorylation to distinguish it from oxidative phosphorylation by mitochondria[23], formerly known to be the only cytoplasmic particles capable of forming adenosine triphosphate Photosynthetic phosphorylation of the kind shown in reaction 1, in which adenosine triphosphate is the sole product of absorbed light energy, has been designated as cyclic photophosphorylation[4] to distinguish it from the non-cyclic photophosphorylation shown in reaction 2, in which only part of the light energy absorbed by chlorophyll is used for the formation of adenosine triphosphate, the remainder is used for the formation of a reductant, reduced triphosphopyridine nucleotide, which provides the 'hydrogens' needed for the conversion of carbon dioxide to sugars (Non-cyclic photophosphorylation has also been called "one-step"[4] or "primary" photophosphorylation[24-26])

---

* The following abbreviations will be used TPN or TPN_{ox}, $TPNH_2$ or TPN_{red}, oxidized and reduced forms of triphosphopyridine nucleotide, ADP, ATP, adenosine di- and tri-phosphopyridine nucleotide, Fe^{3+} cyt, Fe^{2+} cyt, oxidized and reduced forms of cytochrome, FMN_{ox}, FMN_{red}, oxidized and reduced forms of riboflavin phosphate, PN, PNH_2, oxidized and reduced forms of pyridine nucleotide, P, orthophosphate

Non-cyclic photophosphorylation (equation 2) provides all the three expected products of the light phase of photosynthesis in green plants molecular oxygen and the two components of assimilatory power required for the conversion of carbon dioxide into sugars reduced triphosphopyridine nucleotide and adenosine triphosphate Cyclic photophosphorylation (equation 1) supplies only adenosine triphosphate and the participation of this reaction in carbon dioxide assimilation would be needed only if the adenosine triphosphate formed in reaction 2 were insufficient for carbon dioxide assimilation to the level of carbohydrate—a conclusion for which, as will be shown later, there is now experimental evidence

Of the two photochemical reactions of isolated chloroplasts, the less-versatile one, cyclic photophosphorylation, was the more interesting from the point of view of possible mechanisms of energy transformations in photosynthesis Cyclic photophosphorylation (equation 1) permitted us to view the key event of photosynthesis, the conversion of light into chemical energy, as being unrelated to the two corner-stones of photosynthesis in green plants the reduction of carbon dioxide and the evolution of oxygen Instead of producing a reductant for carbon dioxide assimilation, reaction 1 converts the absorbed light energy into a general species of cellular energy, adenosine triphosphate, a highly negotiable physiological "energy currency" which can be used for a multitude of endergonic reactions within the cell[27]

The significance of cyclic photophosphorylation as a general energy conversion process in photosynthesis was greatly increased when it became clear that the structural association of chlorophyll pigments with a phosphorylating system is not limited to green plants but is apparently found in all photosynthetic cells and constitutes a fundamental aspect of photosynthesis[4] Soon after photosynthetic phosphorylation was observed in chloroplasts, Frenkel[28,29] demonstrated photosynthetic phosphorylation in cell-free preparations of a purple, non-sulphur photosynthetic bacterium, *Rhodospirillum rubrum*, a finding confirmed by Geller[30,31] and Mattick and Lindstrom[32] Williams[33], Kamen and Newton[34], and Anderson and Fuller[35] described a photosynthetic phosphorylation in the chromatophores[36,37] of the obligately anaerobic photo-autotroph, *Chromatium*

The photosynthetic phosphorylation found in bacterial chromatophores was of the cyclic type As would be expected from the anaerobic nature of bacterial photosynthesis, chromatophores were unable to carry out non-cyclic photophosphorylation in which the formation of adenosine triphosphate is accompanied by oxygen evolution (equation 2 or 3) Cyclic photophosphorylation appeared, therefore, as a fundamental process, common to all photosynthetic organisms, by which light energy is converted into chemical energy It seemed reasonable to expect that elucidation of the mechanism of cyclic photophosphorylation would prove important to the understanding of the energy conversion process in photosynthesis

Cyclic Photophosphorylation in Chloroplasts and Chromatophores

The first working hypothesis proposed[3] for the mechanism of cyclic photophosphorylation attempted to account, within the framework of van Niel's hypothesis of photolysis of water[5], for several experimental observations The capture of light energy by chloroplasts was not accompanied by oxygen evolution[3,38 39] (or absorption) and was independent of carbon dioxide assimilation[1–3], no reductant was formed or oxidized as a substrate[3,40], the process was (in addition to Mg^{2+}) strongly catalysed by added riboflavin phosphate, vitamin K substances and ascorbate, but not by pyridine nucleotides[3 38,41]

The first hypothesis[3] proposed, visualized cyclic photophosphorylation as resulting in the simultaneous generation, through a photolysis of water, of a reducing agent (H) and an oxidizing agent (OH) at opposite ends of an electron transport chain Vitamin K, riboflavin phosphate, ascorbate and cytochromes were tentatively proposed as members of the electron-transport chain which catalysed a stepwise recombination of the products of photodecomposition of water, thereby making energy available for the formation of pyrophosphate bonds The role of the first electron or hydrogen acceptor was tentatively assigned[3] to either riboflavin phosphate or, as proposed by Wessels[42], to vitamin K

The inadequacy of this hypothesis became apparent when further studies of cyclic photophosphorylation indicated that there are two kinds of cyclic photophosphorylation in chloroplasts Maximal rates of cyclic photophosphorylation occurred with either riboflavin phosphate or vitamin K as catalysts At a saturating concentration of one catalyst, the addition of the other gave no further increase in photophosphorylation, but little phosphorylation occurred unless one of them was added

Riboflavin phosphate and vitamin K appeared to catalyse separate pathways for the electron (or hydrogen) transport which results in cyclic photophosphorylation[26,43,44] The riboflavin phosphate and vitamin K pathways, types or "systems", as they will often be referred to, were found by Whatley *et al* [26,43] to be similar in their requirement for Mg^{2+} and ascorbate, their sensitivity to certain inhibitors such as *p*-chloromercuribenzoate and gramicidin and their insensitivity to others, for example, arsenite and antimycin *A* The two pathways for cyclic photophosphorylation differed, however, in that the riboflavin phosphate system was more sensitive to inhibition by *o*-phenanthroline and dinitrophenol than the vitamin K pathway[26,43] Moreover, triphosphopyridine nucleotide, which was in the meantime found to be a catalyst of cyclic photophosphorylation[45], appeared to be required for the riboflavin phosphate pathway but not for the vitamin K system[26,43] The association of the riboflavin phosphate pathway with triphosphopyridine nucleotide was also indicated by the finding that the non-cyclic photophosphorylation with triphosphopyridine nucleotide (equation 2) was as strongly inhibited by *o*-phenanthroline and dinitrophenol as was the cyclic photophosphorylation with riboflavin phosphate[26,43]

Bacterial chromatophores were found to have only the vitamin K pathway of cyclic photophosphorylation The addition of riboflavin phosphate and triphosphopyridine nucleotide was found to be without effect[7,30] Cyclic photophosphorylation in bacterial chromatophores[30,34] as well as in chloroplasts[46] is also known to be catalysed by a non-physiological agent, phenazine methosulphate This process, in both chloroplasts and chromatophores, was found to resemble the vitamin K system in being resistant to inhibition by *o*-phenanthroline and dinitrophenol and independent of triphosphopyridine nucleotide[7,26] The common denominator of photo-

Table 1 EFFECT OF CHLORIDE ON PHOTOSYNTHETIC PHOSPHORYLATION BY ISOLATED CHLOROPLASTS (ref 6)
(μmoles phosphate esterified)

Phosphorylating system	− Chloride	+ Chloride
(*A*) Non-cyclic, ferricyanide	0 3	3 7
(*B*) Non-cyclic, TPN	0 7	3 6
(*C*) Cyclic, riboflavin phosphate	2 4	7 4
(*D*) Cyclic, vit K$_3$	7 3	8 7
(*E*) Cyclic, phenazine methosulphate	8 3	8 3

In all treatments the reaction mixture (3 ml total volume) contained, in μmoles *tris*(hydroxymethyl)aminomethane (adjusted to *p*H 8 2 with acetic acid), 80, adenosine diphosphate, 10, K$_2$HP^{32}O$_4$, 10, magnesium sulphate, 5 Special additions in the respective treatments were (*A*) ferricyanide, 8 μmoles, (*B*) triphosphopyridine nucleotide, 4 μmoles, chloroplast extract (ref 45) (CE) equivalent to 2 mgm chlorophyll, (*C*) riboflavin phosphate, 0 1 μmole, triphosphopyridine nucleotide, 0 3 μmole, sodium ascorbate, 5 μmoles, (*D*) vit K$_3$ (menadione), 0 3 μmole, sodium ascorbate, 5 μmoles, (*E*) phenazine methosulphate, 30 μgm 'Broken' chloroplasts free of chloride (ref 6) and containing 0 25 and 0 1 mgm chlorophyll were added to the non-cyclic and cyclic systems, respectively 10 μmoles potassium chloride were added to the 'plus chloride' treatment Gas phase, nitrogen Illumination, 30 min in all treatments, except (*E*) illuminated 15 min Other methods are described elsewhere (ref 40)

synthesis in chloroplasts and chromatophores could thus be narrowed down specifically to the vitamin K type of cyclic photophosphorylation

Role of Chloride

Fresh support for the existence of separate pathways for electron transport in photosynthetic phosphorylation has come from the recent work of Bové *et al*[6] on the role of chloride in photosynthesis Warburg[47] discovered that chloride, replaceable by bromide but not by other anions, was essential for oxygen evolution by isolated chloroplasts This discovery was fully confirmed by Arnon and Whatley[48], but they were disinclined to accept, at that time, Warburg's conclusion that chloride is a coenzyme of photosynthesis, because this conclusion would have conferred on chloride the then unwarranted status of an essential element for green plants However, they envisaged the possibility[48] which has since been documented[49,50], that chloride may prove to be an essential micronutrient for green plants

A re-investigation[6] of the role of chloride in the photochemical reactions of chloroplasts (Table 1) confirmed Warburg's conclusion that chloride is essential for photosynthesis in green plants Chloride was found to be required for the non-cyclic photophosphorylations (equations 2 and 3) and for the riboflavin phosphate pathway of cyclic photophosphorylation, all three reactions being known to occur only in chloroplasts Chloride was not required, however, for the vitamin K pathway of cyclic photophosphorylation[6] which is the only type of photophosphorylation shared by bacterial particles and chloroplasts Thus, in the absence of chloride, chloroplasts behaved like bacterial chromatophores, they were able to carry out only the vitamin K pathway of cyclic photophosphorylation

Mechanisms of Cyclic Photophosphorylation

If it is accepted that the vitamin K pathway of cyclic photophosphorylation represents the simplest common denominator of photosynthesis in green plants and bacteria, then a mechanism for this reaction would be expected to provide a basic pattern for the conversion of light into chemical energy The salient facts which must be explained are that a "high-energy" pyrophosphate bond is formed at the expense of absorbed light energy There is no need, *a priori*, to connect this reaction with either photolysis of water or reduction of carbon dioxide Cyclic photophosphorylation produces neither a reductant for carbon dioxide assimilation nor molecular oxygen, the sole product is adenosine triphosphate

The formation of adenosine triphosphate is a familiar biochemical process in all living cells[27] It is commonly encountered in glycolysis and respiration, in which the formation of the high-energy pyrophosphate bond occurs at the expense of energy released during the transport of electrons (or hydrogens) from an electron donor (substrate) to an electron acceptor In respiration the ultimate electron acceptor is molecular oxygen through a series of reactions which result in the formation of water

The simplest hypothesis to account for the formation of adenosine triphosphate in cyclic photophosphorylation is to assume that, as in the dark reactions of respiration, the formation of a pyrophosphate bond is also coupled with a release of energy during an electron transport process However, there is a basic difference between the two in that the electron transport in cyclic photophosphorylation occurs within a "closed", cyclic system from which electrons are not removed, as they are in respiration when they are finally accepted by oxygen In respiration the energy of a substrate has been consumed when it has donated its electrons to oxygen In cyclic photophosphorylation the "energy substrate" which is consumed is light The mechanism by which this is accomplished must therefore provide for a recurrent addition of energy by light to the electrons travelling within the "closed circuit" of cyclic photophosphorylation, thereby raising them to a high energy-level Phosphorylation would then occur at the expense of energy released during a "downhill" transport of the electron from a high to a low energy status in the course of its cyclic pathway A diagrammatic representation of this concept is given in Fig 1

These considerations lead to the following hypothesis for cyclic photophosphorylation The primary photochemical reaction is visualized as being of the photo-oxidation type studied by G N Lewis and his school, in which a light-absorbing molecule, in this instance chlorophyll (attached to a protein component), becomes "excited" and acquires a tendency to expel an electron as well as a capacity to accept one as a replacement for the electron which is being expelled The expelled electron is raised to a high-energy potential at the expense of the absorbed quantum of light energy The proposed hypothesis suggests that the light energy acquired in this manner is transformed into chemical energy in the course of the "downhill" return of the electron to the chlorophyll system via a series of enzyme systems which act as the "transformers" for converting light energy into chemical energy These enzymatic transformations constitute the energy conversion process in photosynthesis

The return of the electron restores the chlorophyll molecule to its ground-state, and the system is ready again to accept a light quantum and repeat the process Chlorophyll can, of course, also be restored to the ground-state when the expelled electron returns directly without going through the enzymatic "energy transformer stations", but in that case electron energy has not been converted into chemical energy and hence photosynthesis has not occurred Instead, a light quantum is emitted and the characteristic fluorescence of chlorophyll is observed

The primary photochemical reaction, in which an absorbed light quantum "excites" a chlorophyll

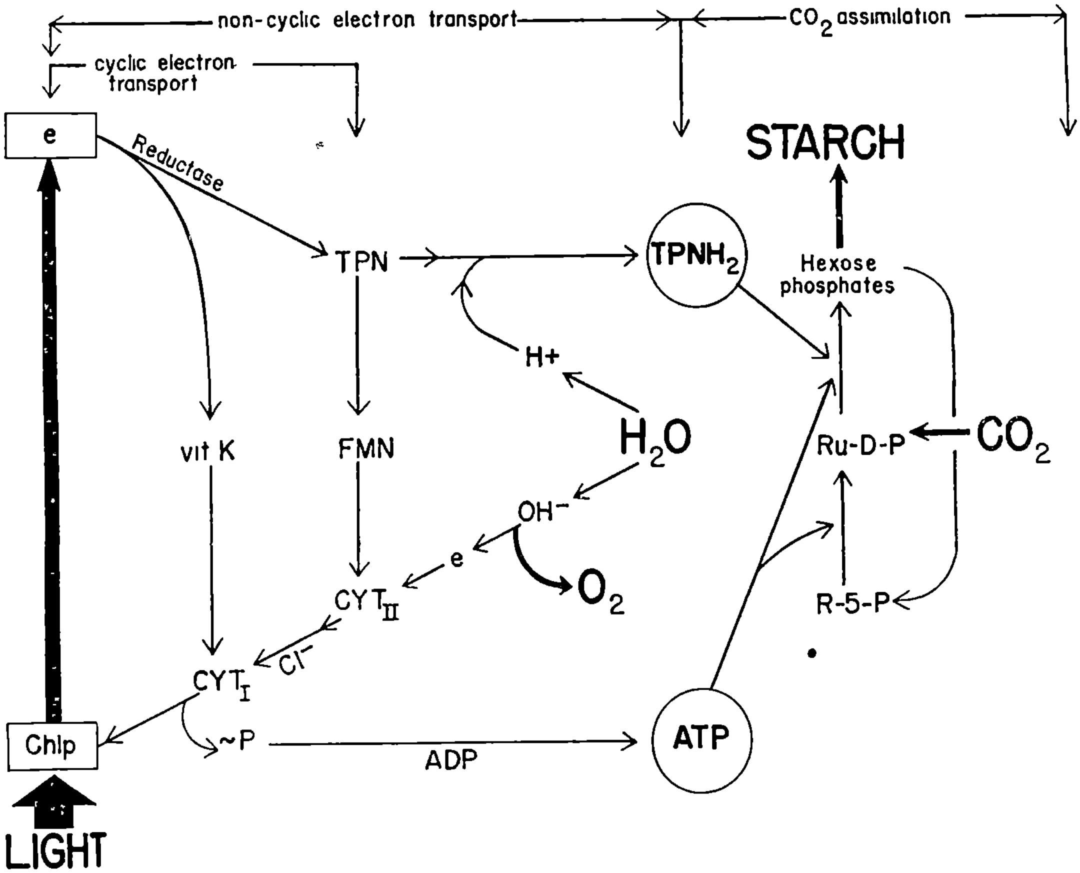

Fig. 1. Proposed scheme for photosynthesis. Chlorophyll, on absorbing a light quantum, becomes 'excited' and expels electrons which have been raised to a high energy-level. In both green plants and photosynthetic bacteria the energy thus acquired from the absorbed light is converted into the pyrophosphate bond-energy of adenosine triphosphate (ATP) during the 'downhill' return of electrons to chlorophyll by a cyclic electron transport system of the vitamin K type. In green plants there is a second cyclic electron transport system of the riboflavin phosphate (FMN) type for forming adenosine triphosphate and also an 'open', non-cyclic mechanism which transports electrons from chlorophyll to triphosphopyridine nucleotide (TPN). In the non-cyclic mechanism the electrons accepted by triphosphopyridine nucleotide are replaced by those donated to chlorophyll by OH$^-$ ions, with a resulting evolution of oxygen. Cytochrome (cyt) components are visualized in the electron transport chain of the cyclic and non-cyclic mechanisms. It is suggested that photosynthetic bacteria use light energy only for the formation of adenosine triphosphate by the vitamin K type of cyclic photophosphorylation. Green plants, however, require both the cyclic and non-cyclic electron transport systems for the formation of assimilatory power, that is, adenosine triphosphate and reduced triphosphopyridine nucleotide (TPNH$_2$). These two substances are then used for assimilation of carbon dioxide to the level of sugar and starch in a series of dark reactions involving the regeneration of ribose-5-phosphate (R-5-P) and ribulose diphosphate (Ru-D-P). Further details are given in the text

molecule and "expels" an electron is represented by equations 4 and 4*a*. The symbol (Chlp)$^+$ is intended to denote that the chlorophyll molecule as it expels an electron becomes ready to accept another and in this way returns to a normal state (cf. "odd ion"[51]).

$$\text{Chlp} + h\nu \longrightarrow \text{Chlp}^* \qquad (4)$$

$$\text{Chlp}^* = (\text{Chlp})^+ + \text{electron} \qquad (4a)$$

The observed cyclic photophosphorylation reactions of isolated chloroplasts and bacterial chromatophores are best explained by a hypothesis that the electron expelled in the primary photochemical reaction is restored to chlorophyll by one of two enzymatic pathways corresponding to the vitamin K and the riboflavin phosphate types of cyclic photophosphorylation. The path of electrons in each of the two pathways will now be traced separately (cf. Fig. 1).

In the vitamin K pathway, it is visualized that two electrons from reaction 4 (written below for schematic clarity as equation 4*b*) are transferred to an oxidized form of vitamin K, giving reduced vitamin K (equation 5). Reduced vitamin K is in turn oxidized by a cytochrome component (cyt$_I$), which may be different in green plants and photosynthetic bacteria but which is in both cases closely associated with the photosynthetic apparatus (equation 6). The cytochrome reduced in reaction 6 donates electrons to the excited chlorophyll from reaction 4, in a "terminal" reaction (equation 7) which restores the chlorophyll to its normal ground-level and produces an oxidized cytochrome. It is visualized that phosphorylation is coupled with the oxidation of this terminal cytochrome component in a manner analogous to the phosphorylations which accompany the oxidation of cytochromes by mitochondria[52].

$$2\,(\text{Chlp} + h\nu) \longrightarrow 2\,(\text{Chlp})^+ + 2\text{ electrons} \qquad (4b)$$

$$\text{Vit K}_{\text{ox}} + 2\text{ electrons} \longrightarrow \text{Vit K}_{\text{red}} \qquad (5)$$

$$\text{Vit K}_{\text{red}} + 2\,\text{Fe}^{3+}\text{cyt}_{\text{I}} \longrightarrow \text{Vit K}_{\text{ox}} + 2\,\text{Fe}^{2+}\text{cyt}_{\text{I}} \qquad (6)$$

$$2\,\text{Fe}^{2+}\text{cyt}_{\text{I}} + 2\,(\text{Chlp})^+ + \text{ADP} + \text{H}_3\text{PO}_4 \longrightarrow 2\,\text{Fe}^{3+}\text{cyt}_{\text{I}} + 2\,\text{Chlp} + \text{ATP} \qquad (7)$$

$$\text{Sum} \quad \text{ADP} + \text{H}_3\text{PO}_4 + 2\,h\nu \longrightarrow \text{ATP} \qquad (1)$$

The sum of reactions 4*b*, 5, 6 and 7 would result in a cyclic photophosphorylation as represented earlier by equation 1, in which light is the "energy-substrate" which is being consumed. It is quite possible that reaction 6, the oxidation of reduced vitamin K, is also coupled with phosphorylation, as was suggested by the model reactions proposed by Wessels[42], Harrison[53] and Clark, Kirby and Todd[54], thereby increasing the total number of phosphorylations which result from the cyclic transport of two electrons in the overall reaction 1

The proposed mechanism for the vitamin K pathway is regarded as the simplest pattern common to green plants and photosynthetic bacteria for converting light into a single form of chemical energy, an energy-rich pyrophosphate bond All other energy conversion reactions in photosynthesis would therefore be expected to be modifications of this basic design

If this basic postulation is correct, it follows that cyclic photophosphorylation should be abolished if the electrons are prevented from completing the cycle by a transfer to an external electron acceptor To be convincing, such an experiment should be carried out with an electron acceptor which would be free from the suspicion that it prevented phosphorylation by acting as an uncoupler, or in some toxic manner

An electron acceptor which fulfils these requirements is ferricyanide It does not uncouple or otherwise inhibit photophosphorylation since its reduction by illuminated chloroplasts is accompanied by a phosphorylation (equation 3) of the non-cyclic type[4,22] Moreover, as shown by Jagendorf[55] and confirmed in this laboratory, ferricyanide has a great affinity for electrons released during the illumination of chloroplasts Ferricyanide added to a vitamin K or phenazine methosulphate system becomes reduced and cyclic photophosphorylation is replaced by the non-cyclic type until all the ferricyanide has reacted

As was mentioned earlier, the non-cyclic photophosphorylation with ferricyanide (equation 3) requires chloride[6] In the absence of chloride, ferricyanide would still accept electrons from the illuminated chloroplast system, but non-cyclic photophosphorylation could not occur Thus by adding ferricyanide, in the absence of chloride, to a cyclic system of the vitamin K type which is independent of chloride, cyclic photophosphorylation should be inhibited if the proposed hypothesis is correct The cyclic transport of electrons in the closed circuit would be interrupted since the electrons would be removed from the system and used in the reduction of ferricyanide

Table 2 shows that this theoretical prediction has been experimentally verified The addition of ferricyanide abolished cyclic photophosphorylation both in chloroplasts[6] and in chromatophores[7] Adding this ion in its reduced form, as ferrocyanide, was without effect The reduction of ferricyanide with ascorbate either prior to or during illumination of the photosynthetic particles restored in full their capacity for cyclic photophosphorylation The conclusion seemed justified, therefore, that the inhibitory effect of ferricyanide resulted from the capture, by this ion in its oxidized form, of electrons which would have normally travelled the cyclic electron transport route (Fig 1) This conclusion was strengthened by the finding that the inhibition was produced by very low concentrations of ferricyanide This would be expected if, as demanded by the hypothesis, the capture of electrons from the cyclic system left its catalytic components in an oxidized form

Table 2 INFLUENCE OF CHLORIDE ON FERRICYANIDE INHIBITION OF CYCLIC PHOTOPHOSPHORYLATION BY SPINACH CHLOROPLASTS AND BACTERIAL CHROMATOPHORES (*Chromatium*) (refs 6, 7)
(μmoles phosphate esterified in 30 min)

Treatment	Chloroplasts −chloride	 +chloride	Chromatophores −chloride	 +chloride
Control	9 2	9 8	4 9	5 1
Ferricyanide				
1 μmole	0 5	9 1	0 4	0 3
2 μmoles	0 5	8 8	0 5	0 5
3 μmoles	0 5	8 7	0 4	0 4
Ferricyanide, 5 μmoles, reduced by ascorbate*	7 2	7 8	6 2	6 8
Ferrocyanide, 5 μmoles	9 4	9 7	5 4	5 1

* Sodium ascorbate (5 μmoles) was tipped in from a sidearm 15 min after the beginning of the experiment, and illumination was then continued for 30 min

In the chloroplast series the reaction mixture was the same as in the phenazine methosulphate treatment described in Table 1 except that 0 25 mgm chlorophyll was used In the chromatophore series (ref 7) the reaction mixture (final volume, 3 ml) contained dialysed *Chromatium* chromatophores (0 23 mgm bacteriochlorophyll) and dialysed extract, and the following in μmoles *tris*(hydroxymethyl)-aminomethane, *p*H 7 8, 80 , adenosine diphosphate, 10 , labelled potassium phosphate, *p*H 7 8, 10 , magnesium sulphate, 5 , vit K_3, 0 3 , and phenazine methosulphate, 0 1 The 'plus chloride' treatments received 10 μmoles potassium chloride Special additions as indicated Other experimental conditions as described in Table 1

The riboflavin phosphate type of cyclic photophosphorylation is visualized as a modification of the vitamin K type The electron expelled by light from chlorophyll in reaction 4 is also returned by a cyclic pathway but one which includes triphosphopyridine nucleotide and a second cytochrome component (Fig 1), in accordance with equations 8, 9, 10 and 11 The riboflavin phosphate (FMN) pathway is completed when the reduced terminal cytochrome component (cyt_I) formed in reaction 11 reacts with chlorophyll through reaction 7, as in the vitamin K pathway

$$2\ (\text{Chlp} + h\nu) \longrightarrow 2\ (\text{Chlp})^{+} + 2\ \text{electrons} \qquad (4b)$$

$$\text{TPN}_\text{ox} + 2\ \text{electrons} \xrightarrow{\text{reductase}} \text{TPN}_\text{red} \qquad (8)$$

$$\text{TPN}_\text{red} + \text{FMN}_\text{ox} \longrightarrow \text{TPN}_\text{ox} + \text{FMN}_\text{red} \qquad (9)$$

$$\text{FMN}_\text{red} + 2\ \text{Fe}^{3+}\text{cyt}_\text{II} \longrightarrow \text{FMN}_\text{ox} + 2\ \text{Fe}^{2+}\text{cyt}_\text{II} \qquad (10)$$

$$2\ \text{Fe}^{2+}\text{cyt}_\text{II} + 2\ \text{Fe}^{3+}\text{cyt}_\text{I} \xrightarrow{\text{Cl}^-} 2\ \text{Fe}^{3+}\text{cyt}_\text{II} + 2\ \text{Fe}^{2+}\text{cyt}_\text{I} \qquad (11)$$

$$2\ \text{Fe}^{2+}\text{cyt}_\text{I} + 2\ (\text{Chlp})^{+} + \text{ADP} + \text{H}_3\text{PO}_4 \longrightarrow 2\ \text{Fe}^{3+}\text{cyt}_\text{I} + 2\ \text{Chlp} + \text{ATP} \qquad (7)$$

$$\text{Sum} \quad \text{ADP} + \text{H}_3\text{PO}_4 + 2\,h\nu \longrightarrow \text{ATP} \qquad (1)$$

The sum of reactions 4*b*, 8, 9, 10, 11 and 7 would also bring about a cyclic photophosphorylation as represented by equation 1 According to this formulation the riboflavin phosphate pathway shares with the vitamin K pathway the primary photochemical reaction (equation 4) and the same site for phosphorylation (equation 7) By analogy with oxidative phosphorylation in mitochondria[52], the riboflavin phosphate pathway in chloroplasts might also result in additional phosphorylations coupled with reactions 9 and 10, resulting in more than one pyrophosphate bond formed per two electrons

It is postulated that reduced riboflavin phosphate cannot reduce directly the terminal cytochrome component needed in reaction 7 (cyt_I) but can do so only through the intermediary of a second cytochrome component (cyt_II) as shown in reaction 10 This postulation is necessary, since the riboflavin phosphate pathway is dependent on chloride, and, on present evidence[6], the effect of chloride can best be explained by assigning to this ion a catalytic function in a portion of a cytochrome electron transport chain which is represented by equation 11. The riboflavin phosphate pathway would also depend on the special reductase needed for the reduction of triphosphopyridine nucleotide[45,56].

Carbon Dioxide Reduction and Oxygen Evolution

Cyclic photophosphorylation provides the same basic mechanism for forming adenosine triphosphate at the expense of light energy for both green plants and photosynthetic bacteria. But cyclic photophosphorylation cannot, by itself, result in carbon dioxide reduction—it does not supply the necessary reductant. Moreover, the proposed mechanism for cyclic photophosphorylation makes no provision for the most distinctive feature of photosynthesis in green plants, the evolution of oxygen—a feature which distinguishes sharply between photosynthesis in green plants and in photosynthetic bacteria, where oxygen evolution does not occur[5].

In developing a general hypothesis for photosynthesis to embrace both green plants and photosynthetic bacteria there is a choice between two alternatives. One can, as van Niel did[5], postulate that the basic similarity between these two types of photosynthesis is the common photochemical origin of a reductant for carbon dioxide and the precursor for molecular oxygen. Van Niel proposed that the light reaction in both groups of organisms is a photolysis of water which results in the formation of a reduced and oxidized moiety, (H) and (OH). To account for the lack of oxygen evolution in bacterial photosynthesis van Niel pointed to the well-established requirement of this process for an external hydrogen donor. The external hydrogen donor was, in his postulation, required for reducing the (OH) back to water, and in this manner keeping the photosynthetic apparatus in bacteria functioning[5].

With the recognition of cyclic photophosphorylation as a process common to photosynthesis in green plants and photosynthetic bacteria, an alternative hypothesis is now possible which omits photolysis of water as the common photochemical reaction in photosynthesis. The alternative hypothesis proposed here considers oxygen evolution in green plants to result not from a photolysis of water but from an "open" non-cyclic electron transport mechanism which is peculiar to green plants. In photosynthetic bacteria a precursor of oxygen would not be formed, and hence there would be no need to postulate that the function of the external hydrogen donor in bacterial photosynthesis is to reduce a precursor of oxygen. According to the present hypothesis an external hydrogen donor is needed in bacterial photosynthesis to supply hydrogens (probably via pyridine nucleotides) for carbon dioxide reduction. In this view what is common to both types of photosynthesis is a mechanism for formation of adenosine triphosphate by a photochemical reaction; what is different is the manner of supplying the reductant for carbon assimilation. Oxygen evolution by green plants becomes merely a consequence of the special way in which they form reduced triphosphopyridine nucleotide in light.

Recent experiments of Ogata *et al.*[7] support the proposal that in photosynthetic bacteria the external hydrogen donor reduces pyridine nucleotides independently of light. Chromatophores isolated from *Chromatium* cells, grown with either thiosulphate or hydrogen gas as the external hydrogen donor, were found[7] to contain an active hydrogenase, capable of reducing pyridine nucleotides with molecular hydrogen in the dark. On the basis of present evidence, the similarities and differences in photosynthesis of green plants and bacteria (represented here, for the sake of simplicity, by *Chromatium* grown with hydrogen gas as the external hydrogen donor) can be summarized as follows:

PHOTOSYNTHESIS

	GREEN PLANTS	PHOTOSYNTHETIC BACTERIA (*Chromatium*)
LIGHT PHASE	*Cyclic photophosphorylation* $ADP + P \longrightarrow ATP$ *Non cyclic photophosphorylation* $2TPN + 2H_2{}^{*}O + 2ADP + 2P \longrightarrow 2TPNH_2 + {}^{*}O_2 + 2ATP$	*Cyclic photophosphorylation* $ADP + P \longrightarrow ATP$
DARK PHASE	*Carbon assimilation* $CO_2 + 2TPNH_2 + n\ ATP \longrightarrow (CH_2O) + H_2O + 2TPN + n\ ADP + n\ P$	*Pyridine nucleotide reduction* $2PN + 2H_2 \longrightarrow 2PNH_2$ *Carbon assimilation* $CO_2 + 2PNH_2 + n\ ATP \longrightarrow (CH_2O) + H_2O + 2PN + n\ ADP + n\ P$
	Sum $CO_2 + 2H_2{}^{*}O \xrightarrow{\text{light}} (CH_2O) + {}^{*}O_2 + H_2O$	Sum $CO_2 + 2H_2 \xrightarrow{\text{light}} (CH_2O) + H_2O$

The non-cyclic electron transport process which, in photosynthesis of green plants, results in a light-dependent reduction of triphosphopyridine nucleotide, evolution of oxygen, and the formation of adenosine triphosphate is visualized as shown in Fig. 1. This process shares with cyclic photophosphorylation the primary photochemical reaction (equation 4) and the phosphorylating site (equation 7). It differs from the cyclic pathway in that the electron expelled in reaction 4 does not return to the chlorophyll molecule but is removed from the cyclic pathway by triphosphopyridine nucleotide, and used (along with the accompanying proton) either for the reduction of carbon dioxide and the formation of carbohydrates during normal photosynthesis, or, under special conditions, for the production and accumulation of reduced triphosphopyridine nucleotide (equation 2).

To keep the chlorophyll system functional the electrons removed by non-cyclic transport must be continuously replenished. It is suggested that this is accomplished by an interaction between hydroxyl ions (or water) and a cytochrome component peculiar to the photosynthetic apparatus of green plants but absent in photosynthetic bacteria. This reaction, represented by equation 14, is visualized as being possibly an 'anode'-type dark reaction, in which

OH^- ions yield molecular oxygen and donate electrons, via a cytochrome chain (equations 14, 11, 7), to chlorophyll, where they are raised, at the expense of absorbed light energy, to the reducing potential required in photosynthesis. The protons (equation 12) are donated to triphosphopyridine nucleotide as it is reduced (equation 13) and, in combination with electrons, provide the hydrogen atoms used in the formation of carbohydrates. A corollary of the scheme is that water, though not undergoing photolysis, is still the source of the oxygen evolved in photosynthesis by green plants.

The reactions leading to oxygen evolution appear to be thermodynamically feasible, since the energy contribution of one einstein of red light, about 43 kcal., is equivalent to a potential of 1·9 V. per faraday. This is more than sufficient to carry out the half reaction, $2H_2O \rightarrow O_2 + 4H^+ + 4e$, which at 25° and pH 7 has $E'_0 = 0{\cdot}815$ V. per faraday.

The sum of reactions 4*b*, 12, 13, 14, 11 and 7 would, as shown below, result in the non-cyclic type of photophosphorylation (equation 2).

$$2\,(\mathrm{Chlp} + h\nu) \longrightarrow 2\,(\mathrm{Chlp})^+ + 2\text{ electrons} \qquad (4b)$$

$$2\,H_2O \longrightarrow 2\,H^+ + 2\,OH^- \qquad (12)$$

$$\mathrm{TPN_{ox}} + 2\,H^+ + 2\text{ electrons} \xrightarrow{\text{reductase}} \mathrm{TPNH_2} \qquad (13)$$

$$2\,OH^- + 2\,\mathrm{Fe^{3+}cyt_{II}} \longrightarrow 2\,\mathrm{Fe^{2+}cyt_{II}} + 1/2\,O_2 + H_2O \qquad (14)$$

$$2\,\mathrm{Fe^{2+}cyt_{II}} + 2\,\mathrm{Fe^{3+}cyt_{I}} \xrightarrow{Cl^-} 2\,\mathrm{Fe^{3+}\,cyt_{II}} + 2\,\mathrm{Fe^{2+}cyt_{I}} \qquad (11)$$

$$2\ \mathrm{Fe^{2+}cyt_{I}} + (\mathrm{Chlp})^+ + \mathrm{ADP} + H_3PO_4 \rightarrow 2\,\mathrm{Fe^{3+}cyt_{I}} + 2\,\mathrm{Chlp} + \mathrm{ATP} \qquad (7)$$

$$\text{Sum: } \mathrm{TPN} + 2\,H_2O + \mathrm{ADP} + H_3PO_4 + 2\,h\nu \longrightarrow \mathrm{TPNH_2} + 1/2\,O_2 + \mathrm{ATP} + H_2O \qquad (2)$$

The non-cyclic photophosphorylation (equation 3) coupled with the reduction of ferricyanide (represented here by Fe^{3+}) is regarded as a variant of the triphosphopyridine scheme in which reaction 13 has been replaced by reaction 15.

$$2\,Fe^{3+} + 2\text{ electrons} \longrightarrow 2\,Fe^{2+} \qquad (15)$$

The sum of reactions 4*b*, 15, 12, 14, 11 and 7 would then result in the non-cyclic photophosphorylation represented by equation 3.

Ferricyanide was already used (Table 2) to demonstrate that, without chloride, chloroplasts behaved like chromatophores. Ferricyanide was also used in the presence of chloride (Table 2) to show that the non-cyclic electron transport system is absent in bacterial photosynthesis. When chloride was added to the reaction mixture the inhibition of cyclic photophosphorylation by ferricyanide was overcome in the case of chloroplasts but not of chromatophores. This would be expected if the chloroplasts were able to complete the non-cyclic electron transport system via reactions 14 and 11 resulting in oxygen evolution. Oxygen evolution would proceed until all the ferricyanide was reduced, at which time the inhibition of cyclic photophosphorylation would disappear. In the case of chromatophores the addition of chloride would not overcome the ferricyanide inhibition of cyclic photophosphorylation since the bacterial system cannot carry out the non-cyclic electron transport in which ferricyanide is reduced and oxygen is released.

Cytochromes in Photosynthetic Cells

The proposed hypothesis assigns an important role in the photosynthetic process to cytochromes. This is based on extensive research in other laboratories. Hill, Scarisbrick and Davenport[57-60] found that the hæmatin content of leaves is much higher than that of other plant tissue. They found that a new cytochrome component, *f*, was found only in green tissues, and, as shown by Davenport[58], was confined to chloroplasts. Hill[59] has also identified another cytochrome characteristic of chloroplasts, cytochrome b_6. Elsden, Kamen, Vernon and Newton[61-64] isolated characteristic cytochrome components, one of which resembles cytochrome *c*, from photosynthetic bacteria of both the facultative and the strictly anaerobic photoautotrophic type.

Another basic premise of the proposed theory is that the cytochromes active in the photosynthetic apparatus become predominantly oxidized on illumination (cf. equation 7). This is necessary for photosynthetic phosphorylation, but, in the case of green plants, also for oxygen evolution. It is the predominantly oxidized state of cytochromes which is considered to provide the requisite positive potential on which the evolution of oxygen from OH^- ions would depend. Evidence from several laboratories indicates that oxidation of cytochromes promptly follows the illumination of photosynthetic pigments. Lundegardh[65] found that on illumination of *Chlorella* cells, leaves or leaf homogenates, cytochrome *f* becomes predominantly oxidized. The oxidation of cytochrome components of algæ and photosynthetic bacteria following illumination, was reported by Duysens[66], Chance and Sager[67], Chance and Smith[68], Olson and Chance[69] and Smith and Ramirez[70]. Of interest in this connexion is also the report of Nieman and Vennesland[71] on the presence of a cytochrome photo-oxidase in chloroplasts.

It appears that despite variation in methods and experimental materials the evidence from different laboratories supports the principal conclusion that oxidation of cytochrome components follows illumination of photosynthetic cells. Although it is premature at this time to equate the cytochrome reactions postulated here with known cytochrome components or to assume that the complete photosynthetic cytochrome chain is already known, it seems likely that the cytochromes already found to be specific to chloroplasts and photosynthetic bacteria will prove to be involved in the postulated reactions or their equivalents.

Cyclic Photophosphorylation and Carbon Dioxide Assimilation in Green Plants

In developing the theme that cyclic photophosphorylation is a mechanism shared by all photosynthetic cells it was implied, but not proved, that in carbon dioxide assimilation, green plants, like photosynthetic bacteria, still depend on this mechanism for adenosine triphosphate formation although they have evolved the non-cyclic type (reaction 2) of photophosphorylation which is peculiar to them. Stated in other terms, it was implied that adenosine triphosphate formed by reaction 2 alone is insufficient for the assimilation of carbon dioxide to the level of carbohydrate.

Experimental evidence for the participation of cyclic photophosphorylation in carbon dioxide assimilation by chloroplasts had to be sought in a system different from the one described before[10]

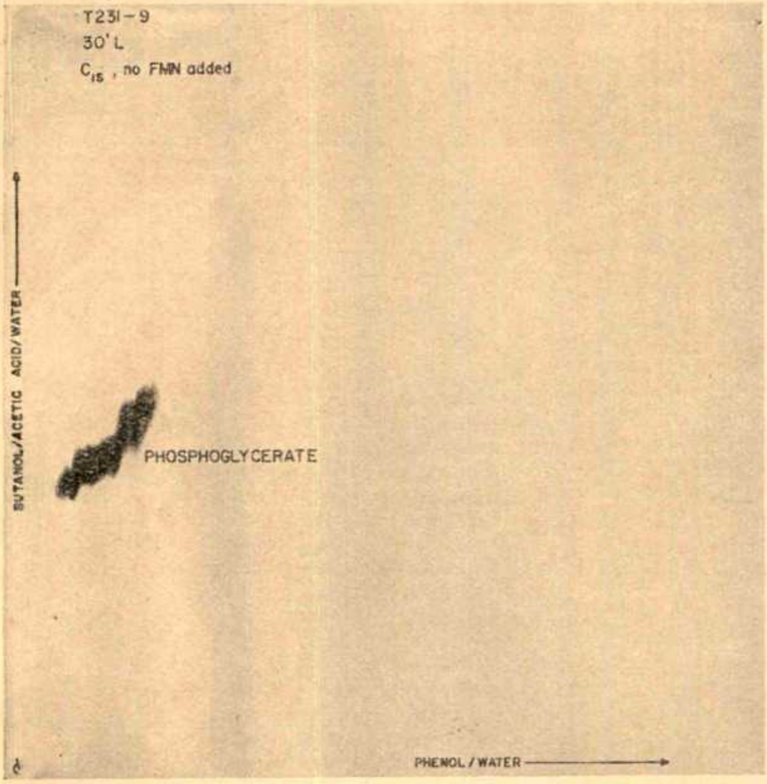

Fig. 2. Radio-autograph of a chromatogram showing products of photosynthetic $^{14}CO_2$ assimilation by illuminated chloroplasts in the absence of added riboflavin phosphate (cf. refs. 8, 24)

in which reduced triphosphopyridine nucleotide and adenosine triphosphate were first generated in substrate amounts by means of reaction 2, and then used later for the assimilation of carbon dioxide in the dark. Here reduced triphosphopyridine nucleotide and adenosine triphosphate were already supplied in excess and a second reaction for generating adenosine triphosphate would be superfluous. However, evidence for the participation of cyclic phosphorylation in carbon dioxide assimilation by isolated chloroplasts was recently obtained by Trebst *et al.*[8,24] in a catalytic system, that is, one in which, as in an intact cell, reduced triphosphopyridine nucleotide and adenosine triphosphate were present in *catalytic* amounts and carbon dioxide fixation was therefore possible only in the light while reduced triphosphopyridine nucleotide and adenosine triphosphate were being continuously regenerated at the expense of absorbed light energy.

Carbon dioxide assimilation in this catalytic system was investigated, under three conditions: (*a*) when the photochemical phase was limited to non-cyclic photophosphorylation reaction (reaction 2); (*b*) when the photochemical phase was limited to cyclic photophosphorylation (reaction 1); and (*c*) when the photochemical phase included both reactions 1 and 2.

Figs. 2 and 3 show that under conditions (*a*) and (*b*) carbon dioxide assimilation was limited almost entirely to the formation of phosphoglycerate. As shown in Fig. 4, the formation of sugar phosphates, which is taken as a measure of a reductive (photosynthetic) carbon dioxide assimilation in this reconstituted chloroplast system, was observed only in case (*c*) when a proper balance was established between the non-cyclic photophosphorylation reaction (equation 2) and cyclic photophosphorylation (equation 1).

In the experiments illustrated by Figs. 2, 3 and 4 the balance between the non-cyclic and cyclic photophosphorylation was maintained by adding different amounts of one of the catalysts of cyclic photophosphorylation, riboflavin phosphate, vitamin K or phenazine methosulphate. Concordant results were also obtained by Trebst *et al.*[8] with inhibitor experiments. For example, using the uncoupling effect of ammonia[55] on both cyclic and non-cyclic

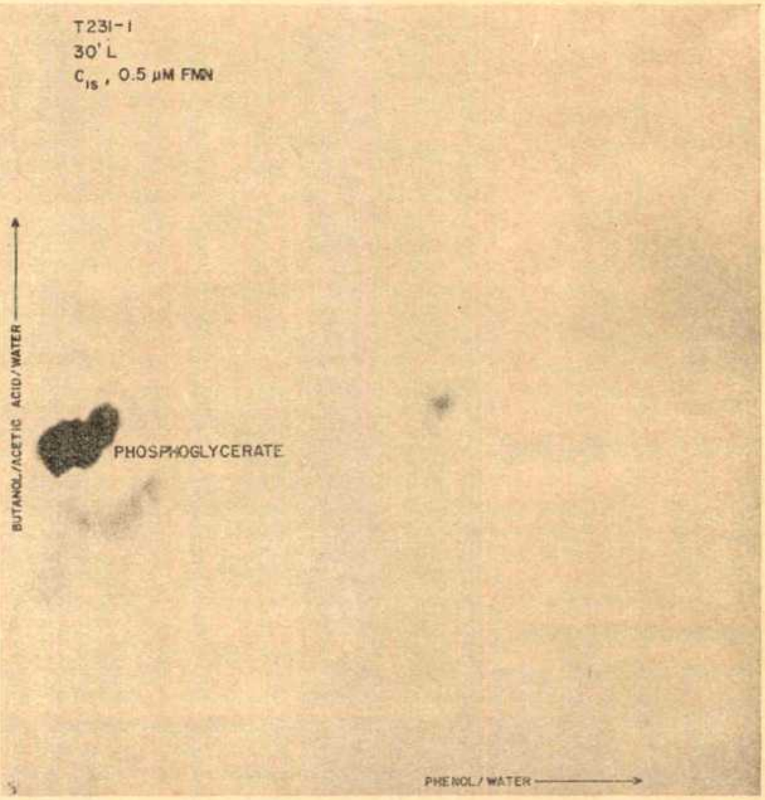

Fig. 3. Radio-autograph of a chromatogram showing products of photosynthetic $^{14}CO_2$ assimilation by illuminated chloroplasts supplied with 0·5 μmole riboflavin phosphate (cf. refs. 8, 24)

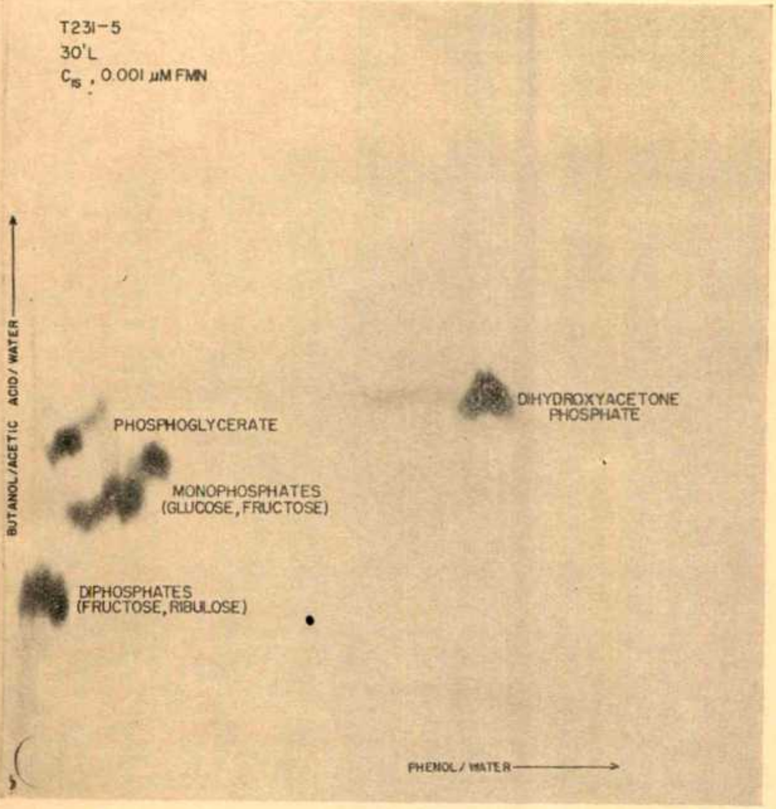

Fig. 4. Radio-autograph of a chromatogram showing products of photosynthetic $^{14}CO_2$ assimilation by illuminated chloroplasts supplied with 0·001 µmole riboflavin phosphate (cf. refs. 8, 24)

photophosphorylation it was possible to suppress the formation of adenosine triphosphate by illuminated chloroplasts (reactions 1 and 2) without inhibiting the reduction of triphosphopyridine nucleotide in reaction 2. Under these conditions, carbon dioxide fixation was completely abolished except when the "acceptor" substance for carbon dioxide was ribulose diphosphate. In that case a single product, phosphoglyceric acid, was formed by the carboxylase reaction (cf. review ref. 72), which does not depend on added adenosine triphosphate; but in the absence of adenosine triphosphate, the phosphoglyceric acid was not reduced by the reduced triphosphopyridine nucleotide.

Parallel experiments of Losada *et al.*[9] on specific enzyme systems in chloroplasts fortified these lines of evidence and supported the conclusion, that in a reconstituted "catalytic" chloroplast system (in which carbon dioxide assimilation can occur only in the light) non-cyclic photophosphorylation alone (reaction 2) does not provide sufficient adenosine triphosphate for a reductive assimilation of carbon dioxide to the level of carbohydrate. Additional adenosine triphosphate must be supplied by cyclic photophosphorylation (equation 2).

General Comments

Modified elements of the proposed hypothesis have been considered by other authors (cf. review ref. 21). The first comprehensive theoretical proposal for a role of adenosine triphosphate in photosynthesis, within the framework of the photolysis of water hypothesis was formulated by Ruben[73] in 1943. Shortly thereafter, Emerson, Stauffer and Umbreit[74] proposed that the "sole function of light energy in photosynthesis is the formation of 'energy-rich' phosphate bonds". They included in this generalization both green plants and photosynthetic bacteria, and made no provision for a photochemical generation of a reductant for carbon dioxide assimilation by green plants. But the main reason why their proposal has met with little acceptance in the ensuing years was the lack of substantial experimental evidence in their experiments with *Chlorella* (cf. refs. 75, 76) for participation of phosphorus in photosynthesis.

With respect to cytochromes, Davenport and Hill[60] suggested that the primary photochemical process in photosynthesis is the *reduction* of 4 molecules of oxidized cytochrome *f* by one quantum of light which transfers 4 electrons in a reaction resulting in a decomposition of water to give molecular oxygen. They envisaged, then, a dismutation type of reaction, in which half the reduced cytochrome is re-oxidized by oxygen to provide additional energy needed to produce another cytochrome with a more reducing potential. A series of such energy dismutations would, as they envisaged, finally result in the production of a reductant with a potential low enough for carbon dioxide assimilation.

Kamen[77] has suggested that "the splitting of water as such may not be involved in the initial light reaction but can occur instead as a result of the transfer and storage of energy during dark back-oxidations". He proposed that "single quantum events mediate the production of adenosine triphosphate and other high energy compounds" and that "the evolution of oxygen [occurs] as a result of the gradual accumulation of a store of oxidized material. In the case of bacteria, the oxidants are removed by reaction with exogenous H donors".

The hypothesis proposed here rules out the formulation of oxygen precursors in bacterial photosynthesis and assigns to the exogenous hydrogen donors the role of carbon dioxide reductants. But the reduction of carbon dioxide also requires adenosine triphosphate, and what distinguishes photosynthetic from non-photosynthetic bacteria is the ability to form adenosine triphosphate at the expense of light energy by cyclic photophosphorylation. In the case of facultative photoautotrophs, such as the purple bacteria, "light and oxygen are interchangeable"[5]. This is now interpreted as meaning that these organisms use the same carbon dioxide reductants in light and in dark, but have two ways for forming adenosine triphosphate: either anaerobically in the light or aerobically in the dark.

The capacity to transform light energy absorbed by chlorophyll into pyrophosphate bond energy, rather than the photochemical formation of a carbon dioxide reductant, is regarded as the common denominator of photosynthetic metabolism in bacteria and in green plants. Reasons were given elsewhere[4] for considering cyclic photophosphorylation, in the time scale of biochemical evolution, as a "primitive" type of photosynthesis which preceded that now found in green plants.

Viewed in this light, green plants appear to have acquired an "open", non-cyclic type of electron transport for reducing triphosphopyridine nucleotide by a photochemical reaction (equation 2) while retaining cyclic photophosphorylation common to green plants and photosynthetic bacteria. This departure from the "primitive" photosynthetic pattern was made possible by the evolution of suitable enzymes such as the light-dependent triphosphopyridine nucleotide reductase[45,56], and a chloride-dependent cytochrome system, one member of which is assumed to be capable of evolving oxygen from water. With regard to the role of chloride in photosynthetic reactions, it is of interest that Arisz[78] and Van Lookeren Campagne[79] have found a light-dependent chloride absorption in *Vallisneria* leaves.

The main features of the proposed hypothesis explain and reconcile the observed photochemical reactions in green plants and photosynthetic bacteria as they are now known ; but it is expected that other aspects of the hypothesis will be modified and amplified as new facts become known. Despite the basic similarity between cyclic photophosphorylation in green plants and photosynthetic bacteria it is possible that the detailed mechanism of this process may be different in the highly aerobic cellular environment of green plants from that in the strictly anaerobic environment of photosynthetic bacteria. The uncertainty as to the role of ascorbate (cf. ref. 26, 80) is another aspect which must await further clarification. It is also now difficult to explain satisfactorily why, in view of the large concentration of vitamin K in chloroplasts (cf. reviews, refs. 24, 26), additions of catalytic amounts of this substance would still be necessary for cyclic photophosphorylation, unless it is assumed that endogenous vitamin K performs another function in chloroplasts[82], conceivably, by acting in the chloride-dependent electron transport chain. On the other hand, the effect of phenazine methosulphate is consistent with the postulated participation of cytochromes in this process. Singer and Kearney[81] have shown that succinic dehydrogenase as well as "other cytochrome reducing dehydrogenases" react faster with phenazine than with any other known hydrogen acceptor.

Different aspects of photosynthesis received recognition in successive periods of its history. To its discoverers, Priestley and Ingen-Housz, photosynthesis seemed at first a cosmic device for correcting bad air by generating oxygen (dephlogisticated air). For a long period afterwards research in photosynthesis was dominated by the conviction, later shown to be erroneous, that carbon dioxide assimilation was peculiar to photosynthesis. Finally, photolysis of water, as manifested by evolution of oxygen by green plants, came to be regarded as the basic photochemical reaction in photosynthesis. Now it appears that the main feat of photosynthesis, the conversion of light into chemical energy, is, fundamentally, even in green plants, more closely linked with phosphorus than with carbon assimilation. In green plants but not in photosynthetic bacteria this energy-conversion process, geared to phosphorus metabolism, is accompanied by the formation of a carbon dioxide reductant and oxygen evolution.

This investigation was aided by grants from the National Institutes of Health and the Office of Naval Research.

OBITUARIES

Sir William Larke, K B E

SIR WILLIAM JAMES LARKE, who died on April 29, three days after his eighty-fourth birthday, deserves honourable remembrance among scientists for his powerful advocacy of scientific research in the service of industry Born in 1875, educated at Colfe's School, and trained as an engineer with H F Joel and Co , Finsbury, and Siemens Brothers at Woolwich, Larke was engineer and manager of the British Thomson-Houston Company's power and mining department from 1899 until 1912, when he became executive engineer During the First World War he served with the Ministry of Munitions and was appointed director-general of raw materials in 1919

In 1922 Larke accepted an invitation to become director of the National Federation of Iron and Steel Manufacturers and it was here that he found his first experience of organizing co-operative research for an entire industry The result was the establishment of the Iron and Steel Industrial Research Council, of which Sir William was the chairman from 1938 until 1945, and ultimately of the British Iron and Steel Research Association, which now carries on the work

Sir Charles Goodeve, director of the British Iron and Steel Research Association, writes "BISRA is now the largest of the research associations and it may not be generally appreciated that its predecessor operated on a small scale with a headquarters staff of about fifteen acting as the technical department of the British Iron and Steel Federation Under the guidance of Larke and the head of the British Iron and Steel Federation Technical Department, the late Mr E C Evans, a substantial and effective research programme was carried out with a very modest budget, and few can have excelled Larke and Evans in their ability to stretch available funds to the utmost They had no laboratories of their own and much of the programme was carried out by works personnel or in academic institutions under the general direction of committees serviced by the small central staff But this staff also did practical work themselves, and the goodwill built up by Larke in steel companies and in university laboratories meant that facilities were readily provided Between 1924 and 1939 studies of the performance of blast furnaces, open hearth furnaces and rolling mills were carried out and several of the fundamental principles governing efficiency were determined Many of the methods used were basically similar to those which are now known as operational research"

Sir William was sixty when, in 1935, the international symposium on welding organized by the Iron and Steel Institute convinced him of the importance of the new processes for the joining of metals and of the need for an effective programme of fundamental research in this field He was then a member of the advisory council to the Committee of the Privy Council for Scientific and Industrial Research, and with characteristic energy set himself to reorganize the Institution of Welding Engineers and to secure for it the support of such eminent engineers as the late Sir Alexander Gibb, and from the Department of Scientific and Industrial Research and industry the financial backing necessary for a co-operative research organization in welding From the Institute of Welding's Welding Research Council, of which Larke was chairman from its formation in 1936, came research results of great value in the war-effort of 1939–46, and out of it the present British Welding Research Association was formed in 1946

A leader of scientific research rather than a scientist, Larke inspired both affection and respect in those who worked with him, and the impress of his critical and constructive mind remains in many institutions in the field of engineering and metallurgy He was exceptional in his readiness to welcome new ideas late in life, retaining to the end a lively and informed interest in the institutions to which he had given so much, where a generation now in sight of retirement remembers the kindly wisdom of his advice and the high standards of efficiency and service which he set them as their goal

GUY PARSLOE

Prof. William Moffitt

ON December 19, 1958, William Moffitt, associate professor of chemistry in Harvard University, died suddenly of a heart attack at the age of thirty-three in Cambridge, Massachusetts Thus ended a brilliant career which already had a great impact on his chosen field of theoretical chemistry and seemed destined to go on to even higher levels of achievement

Moffitt was born on November 9, 1925, in Berlin His father, a British citizen, was in Germany on a government mission Moffitt's early schooling was by private tutoring, but at the age of eleven he became

R318

a pupil at the Harrow County Boys' School. He proceeded to a first-class honours degree in chemistry at New College, Oxford (1946). Two years of research at Oxford led to a D.Phil. in 1948 and a position with the British Rubber Producers' Research Association at Welwyn, where he enjoyed great freedom to follow his chosen lines of inquiry. In 1953, he went to the United States to become assistant professor of chemistry at Harvard. Only two years later, he was appointed associate professor, one of the youngest to receive this rank.

In 1956, he married Dorothy Silberman of Cambridge, Massachusetts; their daughter Alison was born in July 1958.

Moffitt's papers all deal with the application of quantum mechanics to the problem of the electronic energies of molecules and related optical properties. His earlier publications were prepared at Oxford, where he studied under Prof. C. A. Coulson, with whom he collaborated in a number of applications of molecular orbital theory. A noteworthy product of this collaboration was the introduction of the idea of 'bent bonds'; that is, chemical bonds formed from overlapping atomic orbitals not directed along the line joining the two bonded atoms.

After leaving Oxford, Moffitt continued to publish applications of current methods but was struck with their inadequate quantitative accuracy. He was thereby led to make perhaps his best-known contribution, that of the method of 'atoms in molecules'. He reasoned that one of the causes of the poor results then being obtained in calculations of chemical binding energies was that these rather small energies came out as the difference of two huge energies—the total electronic energies of the molecule and of its separated atoms. Consequently, he worked out a procedure by which the interaction between the atoms was treated as a perturbation and its effects separated from the internal energies of the atoms themselves. The latter were obtained from accurate spectroscopic data on free atoms.

At Harvard, he continued his interest in the theoretical elucidation of the ultra-violet spectra of large conjugated molecules. One contribution was a refinement of the free-electron perimeter model, particularly elegant because of the simplicity of its starting point and the number of experimental observations which it correlates. It has been stated that his work in the spectra of aromatic molecules is comparable in this field "to the importance of the complete theory of the Zeeman effect in interpreting atomic spectra".

In addition to his earlier interests, Moffitt characteristically took full advantage of his new scientific environment. Thus, part of the reason for his entry into the field of optical activity was provided by his interest in the research going on in the Harvard Laboratories concerning helical macromolecules and sterols. A major effort was begun which continued to the time of his death and which, though unfinished, helped to provide structural chemistry with a new tool. Moffitt's theoretical analysis of the problem of the optical activity of helical polypeptides, metal co-ordination compounds, and large ketones guided him to an appreciation of the importance of the circular dichroism and the properties of the absorption bands which are responsible for the optical activity. He demonstrated that such bands could be characterized by parameters, extractable from the rotatory dispersion data, which are sensitive to the nature of the asymmetrical environment of the chromophoric group involved in the transition. It is this structural sensitivity which promises to be so useful to the organic chemist.

This work was a fitting and logical application of the knowledge, skills and experience which Moffitt had acquired earlier. He was thoroughly conversant with the techniques of the theoretical physicist, accomplished in the application of advanced mathematical methods, and at the same time learned in a remarkably wide range of chemistry.

Another area in which he was continuing was the interaction of electronic and nuclear motions, especially in the John-Teller effect. This has to do with the instability of nuclear configurations which would lead to degenerate electronic energy-levels.

Few men had as great an impact at so early an age. The reasons are clear. Few have been endowed with such a sparkling, quick and keen intelligence, with such a capacity for spending long hours in the thorough study of fundamental subjects, with such high standards; and finally, but by no means least, with such a warm, outgoing, and appealing personality. Moffitt had tremendous innate assets and he used them fully and efficiently. His intellectual powers were not only applied to the solution of problems but perhaps even more to their wise selection. He avoided areas where only formal solutions were attainable, with no contact with experience.

Moffitt's quickness of mind was obvious to all, as was his interest and devotion to science. Perhaps not so obvious was the effort he expended, both in self-improvement and in the execution of his ideas. His scientific papers were prepared with great care. Each one went through draft after draft until he had finally hand-written a version that met his exacting standards. The use of refined and proper language was for him a necessity, obviously based on his enjoyment and wide knowledge of English literature. His lectures, both in courses and on special occasions, were prepared with the same care as his manuscripts. They were well-organized, clear, elegantly phrased and beautifully delivered.

Moffitt was much more than a scientist of outstanding distinction; he was a cultivated man in the broadest sense, an enthusiastic athlete, and a human being of rare warmth, friendliness and consideration. His death not only deprives science of a great mind but also takes away for ever from his numerous friends and associates a great spirit.

E. Bright Wilson, jun.

Dr. Gustav J. Kramer

On April 19, Dr. Gustav Kramer, *Abteilungsleiter* at the Max-Planck-Institut fur Verhaltensphysiologie and *Leiter* at the Vogelwarte Radolfzell of the Max-Planck-Gesellschaft zur Forderung der Wissenschaften, fell to his death while endeavouring to collect wild fledgling pigeons during a scientific expedition to Calabria in southern Italy. With his death in his fiftieth year there must be a halt to very promising researches upon the homing, migration and orientation of birds and other animals and upon a multiplicity of allied problems. But such has been the inspiration which he has offered to his students and assistants that we may hope that his ideas will for many years yet continue fertilizing this field of study.

Gustav Kramer was born in Mannheim on March 11, 1910, and came of a wine-growing family. After studying at the Universities of Freiburg, Konigsberg and Berlin, he joined the staff of the Kaiser-Wilhelm-Institut fur medizinische Forschung, working upon the sensory physiology of *Xenopus* and upon the metabolic processes of poikilotherms. In 1934 he was appointed assistant at the joint German–Italian Marine Biological Laboratory at Rovigno d'Istria, and three years later assistant director of the Physiological Department of the Stazione Zoologica at Naples. Here it was that he married an Italian zoologist. During this period he continued his work on the metabolism of poikilotherms, concentrating upon cœlenterates and lizards. From this arose an investigation into the island and mainland races of lizards, with biometrical, genetical and hybridization findings.

It was not until after the Second World War, when he spent two years as lecturer in Heidelberg, that Dr Kramer's life-long interest in birds led him into the field where his name will best be remembered, that of bird orientation, and when, in 1948, he was appointed as a departmental director at the Max-Planck-Institut at Wilhelmshaven he was able to devote most of his energies to investigating this problem. The decade since this appointment has seen the publication of a remarkable series of papers in which he has established the dependence of birds on the Sun and upon an 'internal chronometer' for their feats of orientation, homing and migration. In 1958 the Max-Planck-Gesellschaft recognized Dr Kramer's achievements and promise by appointing him to direct an institute of animal behaviour, which was to be built at a site of his choosing. It is still under construction at Walddorf (Tubingen). Less than three weeks before his death, the Gesellschaft made him director of its Radolfzell bird observatory (formerly the well-known Rossitten bird observatory).

Gustav Kramer was an athlete and climber of some note, and it is ironic that he should have met his death while using his climbing ability in his scientific work. He is survived by his widow and by three children. His unfailing charm and hospitality and the inspiration he gave to his students, staff and scientific acquaintances will be remembered with affection.

D B Carlisle

NEWS and VIEWS

Dr Warren Weaver

On August 1, Dr Warren Weaver retired from his present position as vice-president for the natural and medical sciences of the Rockefeller Foundation. He has been appointed vice-president of the Alfred P Sloan Foundation, and he will continue his activities on the National Science Board, on the National Advisory Cancer Council, on the Council for Library Resources, as vice-chairman of the Health Research Council of the City of New York, and as vice-president and chairman of the Committee on Scientific Policy of the Sloan-Kettering Institute for Cancer Research. For twenty-seven and a half years Dr Weaver has had, within the Rockefeller Foundation, administrative responsibility for all activities in the natural sciences. When the Rockefeller Foundation became active in agriculture in the early 1940's this field was placed under Dr Weaver's general charge. Still more recently, in 1955, he was also assigned supervisory responsibility for the Foundation's activities in the medical sciences.

Astronomy at Glasgow

Prof W M. Smart

Prof W M Smart, regius professor of astronomy in the University of Glasgow since 1937, is to retire on September 30. Prior to 1937 Prof Smart had a background which combined Cambridge mathematics and theoretical astronomy with naval navigation practice and teaching. During this period he was engaged in research in stellar dynamics, particularly with the phenomena of star streaming and stellar motion. His development of a flourishing school of theoretical astronomy in Glasgow was based on this experience. To assist in his teaching work, and to help theoretical astronomy everywhere, he wrote three well-known and widely used astronomical text-books in addition to a number of other books of academic, educational and popular interest. He encouraged his department in studies in stellar motion and other theoretical problems. It is understood he will move to the London area on retirement.

Prof. P A. Sweet

Dr P A Sweet has been appointed to succeed Prof Smart. He has, since 1952, been a lecturer in astronomy at University College, London, and also assistant director of the University of London Observatory. The incoming professor is not new to Glasgow, having lectured there during 1947–52. After completing the Mathematical Tripos at Cambridge in 1946, Dr Sweet commenced theoretical researches in the field of stellar structure and plasma physics. His theory concerning the rate of mixing of the material in stars has had wide consequences in the analysis of stellar structure and evolution. His more recent work has been connected with the influence of magnetic conditions on the control of energy reactions in cosmic material. The applications of his theories to stellar and other problems are still in progress. We may anticipate a development of these and other studies with Dr Sweet's appointment to the regius professorship in astronomy at Glasgow.

Jacob Bell . Founder of the Pharmaceutical Society of Great Britain

On June 12, the hundredth anniversary of his death, tribute was paid by the Pharmaceutical Society of Great Britain to its founder, Jacob Bell, when the president, Mr Gwilym Hughes, unveiled a tablet to Bell's memory in Woodbury Park Cemetery, Tunbridge Wells, where he is buried. By his work for the Society, said Mr Hughes, Jacob Bell was acting in the public interest as well as in the interests of his calling. When he commenced his labours, pharmacy in Great Britain was ill-defined, unregulated and unorganized, without acknowledged standards of education or practice. It had no authoritative means of expression and lacked official recognition.

When Bell died, substantial progress had been made in overcoming these difficulties and the practice of pharmacy had been set upon a path of development which subsequent events had shown to be sound In the evening Mr Hughes gave a review of Jacob Bell's life and work at the Society's House in Bloomsbury Square, where a commemorative exhibition was held during the following week

Charles Cagniard de la Tour (1777–1859)

CHARLES CAGNIARD DE LA TOUR (or Cagniard-Latour), who died one hundred years ago on July 5, 1859, was a distinguished engineer and physicist, who also made original contributions to chemistry and to medicine Born in Paris on March 31, 1777, he attended the Ecole militaire de Rebais and the Ecole polytechnique and qualified as *ingénieur-géographe* In 1811 he was appointed to the Ministry of the Interior, and eight years later was created baron for supplying the Hôpital St Louis and the Usine Royale with gas-lighting He was elected to the Paris Academy of Sciences in 1851 His name is specifically attached to two inventions—a blowing machine and a siren The former, the *cagniardelle,* is an Archimedean screw, immersed obliquely in a tank of water and rotated in a direction opposite to that required for raising water The siren, for determining the number of vibrations corresponding to a sound of any particular pitch, was extensively used for signalling on ships Cagniard de la Tour also experimented on the mechanism of voice production ("Considérations et expériences diverses sur la voix humaine", 1837) In 1822–23 he studied the effects of heat and pressure on liquids and determined for each liquid a definite temperature (later called the critical temperature), above which it did not remain liquid in spite of the highest attainable increase of pressure These investigations were continued and extended by Faraday With Theodor Schwann in Germany he originated the germ theory in 1837 by his discovery that yeast consists of a mass of globules which are vegetable in nature and that it is responsible for fermentation ("Mémoires sur la fermentation vineuse") This theory was promptly abandoned two years later when Liebig insisted that the process was purely chemical, but was resurrected by Pasteur in 1856

British Space Research

IN reply to a question in the House of Lords on July 29, Lord Hailsham said that in their recent visit to the United States to discuss co-operation in the field of scientific research in space using earth satellites, Prof Massey and his small team of experts had had most valuable and fruitful discussions with the National Aeronautics and Space Administration As a result it is proposed the British scientists will prepare instruments for satellites to be placed in orbit by the use of the *Scent* vehicle which the National Aeronautics and Space Administration is developing for use in connexion with civil scientific research Several vehicles might be involved over three to four years These proposals have been approved by the Government subject to the conclusion of formal arrangements Information regarding these programmes and their results will be made available to the international scientific community Both the British and the American groups regard this project as a valuable development in scientific co-operation Meanwhile, the arrangements for design studies of British launches, announced by the Prime Minister, are unaffected

Canadian Committee on Space Research

THE National Research Council of Canada has formed an Associate Committee on Space Research jointly with the Defence Research Board The new Committee will have co-ordination duties and will advise on international co-operation Scientific subjects to be studied will include geomagnetism, the aurora, meteorology, cosmic rays, radiation from the Sun, and chemical composition of the upper atmosphere This Canadian work, now in hand, may be enhanced by series of high-altitude rockets carrying measuring instruments The new Committee will be particularly useful to Canadian university groups interested in research in the upper atmosphere They will have an opportunity to design their own experiments, and to build instruments for the nose cones of rockets The rocket range at Churchill will probably be used Canadian and American groups have already been co-operating in maintaining this range The new Committee includes members from a number of Government departments and agencies, and from universities with research teams in related fields The secretary of the Committee is Mr B D Leddy, National Research Council, Ottawa 2

The *Dragon* Project

THE first meeting of the International Board of Management of the high-temperature reactor project of the Organization for European Economic Co-operation (*Dragon*) was held recently at the Atomic Energy Establishment, Winfrith, Dorset, where the reactor experiment is to be built Dr Sigvard Eklund, of Sweden, was elected chairman of the Board for the current year, with Sir John Cockcroft, of the United Kingdom, as vice-chairman Sir John was succeeded in this office by Sir William Penney on July 1 The Board appointed Mr C A Rennie, of the Atomic Energy Research Establishment, Harwell, as chief executive of the project The Board, which includes representatives of the signatories of the *Dragon* Agreement, namely, Austria, Denmark, Belgium, France, Germany, Italy, Luxembourg, The Netherlands, Norway, Sweden, Switzerland and the United Kingdom, considered and approved a broad programme of work and a budget for the financial year, 1959–60, on the basis of preparatory work by a General Purposes Committee under the chairmanship of Dr J Gueron (Euratom)

The Scripps Institution of Oceanography

THE Scripps Institution of Oceanography has announced its intention to send two ships on an ambitious oceanographic and geophysical investigation of the western Pacific Ocean and eastern Indian Ocean to last six months between February and August 1960 Particular attention will be paid to studies of the sea floor, and to areas such as the Java trench, where previous work has posed specific problems The programme will include dredging, coring, measurements of heat flow, seismic, magnetic and gravity surveys, studies of the interchange of carbon dioxide between sea and air, and sampling for radioisotopes and trace elements The biological programme will consist of plankton sampling and mid-water trawling as well as dredging The memorandum received from the Director of the Scripps Institution says that visiting scientists and suggestions as to subjects for examination will be welcomed

Agricultural Aviation Group

An Agricultural Aviation Group has recently been formed by the Royal Aeronautical Society The aims of the Group are to further the use of aircraft in agriculture, forestry, pest control, fertilizing, seeding, chemical application and similar subjects and to provide facilities for those interested in such matters to meet and exchange ideas and information The formation of the Agricultural Aviation Group was largely inspired by Mr S W G Foster, an Associate Fellow of the Society and a design consultant The Group expects to take an active part in the International Agricultural Aviation Conference which is to be held at Cranfield in September The Agricultural Aviation Group is the second group to be formed within the Society since the Council agreed to the formation of groups to cover small specialized fields of aeronautics An indication of the wide range of the interests of members of the Society is given by the fact that the Society now has an Astronautics and Guided Flight Section, a Man-Powered Aircraft Group, an Agricultural Aviation Group, and, within the next month or two, will also have a Historical Group

Efficient Use of Man-power in Industry

The report of an inquiry undertaken by the National Joint Advisory Council into practices impeding the full and efficient use of man-power has now been published by the Ministry of Labour and National Service (pp 16 London H M Stationery Office, 1959 1*s* net) The inquiry was concerned with restrictive labour practices, and the Council considers that the results of the inquiry are encouraging Some 64 industries reported that they had no problems in regard to the efficient use of man-power and a further 42 had set up machinery to deal with any such problems or appeared to be establishing such machinery Six industries needed more time, or because of various difficulties had been unable to make a joint examination, though some of these industries are of considerable importance in the national economy, and the Council expresses concern about the position in this group In the ship-building and ship-repairing industry there are problems which need to be tackled if greater efficiency is to be achieved and this calls for efforts from both employers and trades unions More generally, the report points out that much depends on the use to which joint machinery is put, but the existence of an organization for joint consultation and the fact that such organization functions will afford some grounds for both hope and confidence

Tyneside Association of Libraries for Industry and Commerce

The Tyneside Association of Libraries for Industry and Commerce was formed last September under the sponsorship of the Northern Regional Board for Industry, the Tyneside Productivity Committee, and the North East Industrial and Development Association Having its headquarters at the Commercial and Technical Department of the Central Library, New Bridge Street, Newcastle upon Tyne 1, the main purpose of the Association is the co-ordination and development of existing facilities in the Tyneside area in order "to help industry and commerce by making information readily and quickly available" Use of the service is available to any one free of charge, membership is open to any firm or organization which maintains a library and/or information department, and is willing to supply non-confidential information on request To reduce the burden on headquarters, the brochure describing the service suggests that inquiries should, in the first place, be directed to the nearest public library, if that fails (or if the matter is urgent) the inquiry may be sent direct to the Association's headquarters The chairman of the Association is R A Cookson, vice-chairman of the Northern Regional Board for Industry The honorary secretary is the Newcastle City Librarian, from whom copies of the brochure may be obtained

Chemical Control of Eelworms on Strawberries

The effectiveness of chemical substances in the control of the several eelworms which infest strawberries has been examined and discussed by R S Pitcher (*J Hort Sci*, 34, No 2, 1959) Although the hot-water treatment gives a satisfactory control of eelworm, it has several disadvantages, notably that it is time-consuming, exacting, and requires precision, and it cannot be used in the field on an already established and growing crop Hence the desirability of discovering chemical methods of control In the present investigation, a number of nematicides were tested under pot conditions and field trials were carried out with parathion All treatments rapidly reduced the symptoms caused by the three eelworm species, but the persistence of the remedial effect varied according to the kind of infestation involved Pre-planting dips were consistently more effective than spraying of established plants in the field With each of the three eelworm species, the level of infestation was greatly reduced by parathion (0 1 per cent of active ingredient), whether used as a drench, spray, or pre-planting dip

Non-Cartridge Type Demineralized Water Units

Water demineralizing, or de-ionizing, units are now superseding the still and distilled water delivered in carboys as a source of supply of purified water for laboratories and similar establishments A feature of many such units, however, is their reliance on detachable cartridges of ion exchange resins which are returned to the supplier when exhausted The Mark 4 and Mark 5 Portable "Deminrolit" plants manufactured by the Permutit Co, Ltd, Gunnersbury Avenue, London, W 4, have been designed for easy 'on the spot' regeneration of the exhausted ion exchange material, thus obviating the need for detachable cartridges and replacements Both plants consist of a pair of sealed columns charged respectively with "Zeo-Karb" cation and "De-Acidite" anion exchange resins, the water being passed through the columns in that order Flexible connexion and delivery tubes, with a multi-valve control system, facilitate operation and regeneration A built-in dial-type conductivity tester enables 'spot' checks to be made on the quality of water being produced By this means the point at which regeneration becomes due may be determined precisely Regeneration involves flushing the cation column with a dilute solution of hydrochloric acid and the anion column with dilute caustic soda or soda ash solution Both columns are then rinsed with water, when the plant is ready for further use Both plants are constructed throughout from non-corrodible materials and operate at normal cold water tap temperatures and pressures

Rutherford Memorial Appointments

UNDER the terms of the scheme to commemorate the late Lord Rutherford of Nelson the following appointments have been made by the Council of the Royal Society Sir Lawrence Bragg has been appointed Rutherford Memorial Lecturer for 1960, to deliver the lecture in New Zealand Mr D J Tritton, now working at the Cavendish Laboratory, Cambridge, has been appointed Rutherford Scholar for 1959 for three years, to investigate the relationship between the manner of production of turbulence in a fluid flow and the large eddy structure of that turbulence, at the department of aeronautical engineering, Indian Institute of Science, Bangalore

Canadian National Research Council Scholarships for 1959–60

THE National Research Council of Canada has granted 399 scholarships for 1959–60, with a total value of 844,600 dollars Three hundred and forty-one of these scholarships are for graduate work at Canadian universities Awards for study abroad include thirty-three special scholarships, to be held in the following countries eighteen in the United Kingdom , fourteen in the United States , and one in France Twenty-five postdoctorate overseas fellowships have been granted for work in the following countries nineteen in the United Kingdom , five in France , and one in the Netherlands

University News

California

A DEPARTMENT of Virology has been established in the University of California at Berkeley Chairman of the new Department is Dr Wendell M Stanley, Nobel laureate and director of the Virus Laboratory Eight faculty members, drawn from the Virus Laboratory, now comprise the staff of the Department Starting in September 1959, lecture courses will be offered to graduate and advanced undergraduate students, to be followed later by a comprehensive laboratory course Additional instruction will be offered, mostly at graduate level, in the form of special study courses, seminars, and research projects

Ibadan

PROF F W SANSOME, professor of botany in University College, Ibadan, Nigeria, has been appointed professor of botany in the University College of Ghana, Achimota He is to be succeeded at Ibadan by Dr E Njoku, at present senior lecturer in the College

London

THE new Sir John Atkins Laboratories, of which Sir John Atkins laid the foundation stone on June 24, will enable important and urgently needed developments to take place at Queen Elizabeth College, London The College is the only institution in Britain that provides courses leading to a degree in nutrition (B Sc Nutrition, London) and shares with the University of Bristol the distinction of preparing students for the only degrees in household science (B Sc Household Science, London) In the new buildings, which will house the Departments of Bacteriology, Biology and Nutrition, more students can be accommodated and much more research in these subjects can be undertaken More accommodation for teaching and research will also be available for the five other science departments which will expand in the present buildings

Michigan

DR WRAY SMITH has been appointed assistant director of the Willow Run Laboratories He will continue to be responsible to the director and associate director of the Willow Run Laboratories for the direction of the administrative staffs of the laboratories and for assisting the director and associate director in formulating and implementing administrative policies and procedures He has been on the Willow Run Laboratories staff since 1954 and has been administrative associate since early in 1958

Prof Louis J Cutrona, professor of electrical engineering in the University of Michigan, has been appointed head of the largest of the several laboratories within Willow Run The Radar Laboratory is involved in major programmes in the field of airborne and ground-based radars with support through Project Michigan, the U S Air Force and the Advanced Research Projects Agency

Announcements

AT the first commencement on June 18, the honorary degree of D Sc was conferred on Dr Peyton Rous and on Dr Herbert S Gasser for their contributions to the development of the Institute and the attainment of its high standards in research and scholarship

SIR HUGH BEAVER was recently elected president of the Royal Statistical Society for the ensuing year Mr B Benjamin, Miss J I Douglas and Dr P Armitage were re-elected honorary secretaries, and Mr R F Fowler was re-elected honorary treasurer

DR F KENNETH BRASTED, former president of the University of Dallas, has joined Texas Instruments Incorporated as administrative director of its Central Research Laboratory

DR MARGARET HANNAH has been awarded the Warner Medal which is given by the Textile Institute for outstanding work in textile science and technology Dr Hannah was formerly a lecturer in textile engineering in the University of Leeds

THE ninth Annual Instrument Symposium and Research Equipment Exhibit will be held during September 28–October 1 at the National Institutes of Health, Bethesda, Maryland Further information can be obtained from James B Davis at the above address

THE third conference on Analytical Chemistry in Nuclear Reaction Technology will be held in Gatlinburg, Tennessee, during October 26–28 Further information can be obtained from C D Susano, Oak Ridge National Laboratory, P O Box Y, Oak Ridge, Tennessee

ERRATUM In the "News and Views" item entitled "Ultrasonic Vibrations at 10,000 Megacycles", published in *Nature* of June 6, p 1570, the work referred to is being carried out by Dr E H Jacobsen, a member of the General Electric Company Research Laboratory, Schenectady, New York, and not by Dr E H Jackson, as printed

MORE LAND-USE PLANNING

WHATEVER posterity may remember of the term of office of the thirty-third President of the United States, Harry S Truman, it is unlikely ever to forget those trenchant sentences of his inaugural address of January 20, 1949, "Fourth, we must embark on a bold new programme for making the benefits of our scientific advances and industrial progress available for the improvement and growth of the under-developed areas For the first time in history, humanity possesses the knowledge and the skill to relieve the suffering of these people" As the programmes then initiated and the other innumerable activities directed towards helping the less developed countries have progressed, it has become increasingly apparent that the knowledge possessed by humanity is far from adequate In no sphere is this more true than in the proper use and management of land in the tropics—whether the humid tropics or the arid The lesson is still being learnt, after a number of major failures, that the secret is to make haste slowly and to build upon a firm foundation of factual knowledge Reference has been made in a recent issue of *Nature* (183, 20 , 1959) to the large-scale land-use maps of the Gambia and Singapore being prepared as a basis for planning, and it is clear that many other countries are working along comparable lines

Among the many research projects undertaken by the Institut National pour l'Étude agronomique du Congo belge (INEAC) is one for a soil and vegetation survey The results are being published as a series of fully coloured small sheets, one of soils and another of vegetation, with an explanatory memoir To date a dozen *livraisons* have been published, or are in the press, but a simple calculation suggests that about 7,000 sheets will be required to cover the whole territory on the scale of 1 50,000 which has been chosen Taking as an example[*] Planchette 3 (Lilanda) of the Yangambi area (Livraison 6) prepared by three soil scientists and a botanist, sixteen soil series and three complexes are distinguished The soils are classified by parent material and by class of drainage—"chaque unité reconnue en fonction de ces deux facteurs reçoit le rang de série" The complexity of the soil picture is accentuated in the vegetation map Small blank areas mark cultivated fields, but even at the scale of 1 50,000 the major vegetation types cannot be shown without recourse to stripes for "mélanges" and small circles in a background for "mosaiques" Such is the true measure of the complex natural environment within which development is to take place

On the western side of the Atlantic a Soils Research and Survey Section under the direction of T A Jones has been set up at the Regional Research Centre of the British Caribbean at the Imperial College of Tropical Agriculture, Trinidad The first three monographs to be published cover the parish of St Catherine, Jamaica, the Rupununi savannahs of British Guiana, and the island of St Vincent[*] The first two have soil maps on a scale of 1 50,000—the first with pink symbols on a black outline, the second in black only, while the St Vincent map comprises three sheets on the scale of 1 20,000 The soils are grouped in St Vincent according to parent material (soils over recent alluvium, old alluvium, limestone, granodiorite, etc) whereas in British Guiana there is a tentative local classification based on geomorphological regions (well-drained soils of the pediments, imperfectly drained soils of elevated flats, etc) The Jamaica monograph combines the two In the explanatory memoirs there are elaborate tabular statements giving the important characteristics of each soil, recommended cultivation practices and crops for each There are detailed descriptions of the soil profiles and a new scheme of 'land capability classes' is introduced In place of the familiar eight classes of the American system, seven are recognized, each divided into *e* (erosion danger), *w* (excess water), *s* (shallow or droughty) and so on In contrast to the Belgian work this is a far more subjective approach it suggests an over-emphasis on soil and perhaps a passing over of lessons to be learnt from existing vegetation and land use In due course it will be most enlightening to know how far the practical recommendations have been followed and the results

Unesco is much concerned with the problems of both the arid and humid tropics Arising out of the Kandy Symposium[†] held in 1956, a vegetation map of the whole of Malaysia (including all New Guinea) has been compiled by C G G J van Steenis and published with the collaboration of Unesco[‡] At a scale of 1 5,000,000 it is highly generalized and approaches the problem of land-use in the humid tropics from a very different point of view—that of the broad overall perspective It has been possible, however, to show a dozen types of forest as well as the main areas of 'savannah', grass, alpine grass, wet rice, dry fields and plantations, making eighteen categories in all

The need for a stock-taking of land resources and of the present use of land is by no means confined to the tropics Wherever there is a heavy pressure of population on land it forces itself upon the attention of governments and research organizations In Italy the Consiglio Nazionale delle Ricerche has undertaken the preparation of a comprehensive Carta della Utilizzazione del Suolo, now being published on the scale of 1 200,000 in 23 sheets[§] The work is under the capable direction of Prof Carmelo Colamonico, who writes an introduction to the first two descriptive memoirs The first is on Calabria (sheets 19 and 20) by Ferdinando Milone , the second, on Sicily (sheets 21, 22 and 23) by the same author. A preliminary sheet of central Italy was shown to the Congress of the International Geographical Union at Washington in 1952 and the maps, in full colour, show twenty categories of land-use following closely the recommended categories laid down by the Commission on the World Land Use Survey. The Survey has since recognized the vital importance of separating irrigated and non-irrigated lands, which has been done on the Italian maps. Anyone familiar with Mediterranean lands will know the intimate mixtures of trees and ground crops—olives with cereals, for example—and will recognize the justification of this mixed category. Little of Sicily is shown as 'sterile' except the higher slopes of Etna.

Though differing widely in their methods and execution, all these maps illustrate the growing recognition that before land can be planned the present position must be surveyed and analysed.

L. DUDLEY STAMP

AGRICULTURAL RESEARCH IN EIRE

AN FORAS TALÚNTAIS (THE AGRICULTURAL INSTITUTE)

AN Foras Talúntais was established under the Agriculture (An Foras Talúntais) Act, 1958, and commenced activities on August 1, 1958. Its functions include reviewing, facilitating, encouraging, assisting, co-ordinating, promoting and undertaking agricultural research in the Republic of Ireland. The Institute has authority to provide, where necessary, new facilities and staff to carry out research, to assist in carrying out specific research projects and to make grants for the extension and development of facilities to scientists actively engaged in agricultural research. The Institute is specifically obliged to disseminate the results of agricultural research, particularly to those engaged in agricultural advisory work. As one of its major and general functions the Institute has a statutory obligation to advise the Minister for Agriculture on any matter relating to agricultural research or agricultural science on which advice is requested by him. As part of its educational activity in the promotion and encouragement of agricultural research, the Institute may provide and organize courses of study in agricultural research and related subjects, and it may also provide and organize seminars, conferences, lectures and demonstrations on agricultural research; it may grant scholarships, and award fellowships to persons who have done outstanding work in relation to agricultural science or agricultural research.

The Institute is an autonomous national body, governed by a Council which consists of a chairman and twelve ordinary members. The chairman is appointed by the President of Ireland. Five members of the Council are nominated by agricultural and rural organizations; the nomination is by means of election by a panel of twenty-five organizations divided into five groups; one member is nominated by each of the governing bodies of the University Colleges of Cork, Dublin and Galway and the Board of Trinity College, Dublin, and the three remaining members are nominated by the Government of the Republic of Ireland. The activities and staff of the Institute are under the control of a director responsible to the Council as chief officer of the Institute. The finances of the Institute are provided for under a number of headings. From the Counterpart Special Account, by arrangement between the United States and the Irish Governments, the Institute has available a capital fund of £840,000 to be expended on capital projects and an endowment fund of £1,000,000. A grant towards the expenses of the Institute will be paid every financial year out of monies provided by the Irish Government. The Institute is empowered to accept gifts of money, land or other property under specified conditions which must be consistent with the functions of the Institute. With regard to gifts and fees for specific research projects, the Institute looks for support particularly to industries and businesses closely associated with agriculture and to farming organizations and individuals interested in agricultural development.

The activities of the Institute have been organized on the basis of a headquarters consisting of a secretariat, scientific and agricultural liaison offices and statistical library and information services, together with five main Research Divisions as follows: (1) Soils, (2) Plant Sciences and Crop Husbandry, (3) Animal Production, (4) Rural Economy and (5) Horticulture and Forestry. The scientific liaison office will make and maintain contact with agricultural research and allied services in other countries, while in addition providing for the scientific development and co-ordination of the research programme at home. The agricultural liaison office will ensure the closest possible contact, co-operation and integration of effort between the Institute, departments of State, the advisory services and the farming community. A specialist advisory service in each facet of agriculture will be provided for advisory officers and others.

The work of the different Divisions is being developed on the following general basis. The Soils Division will carry out research and specialist advisory activities in the spheres of soil physics, soil chemistry and biochemistry, soil microbiology, soil fertility and fertilizer use, plant nutrition and physiology, soil classification and survey, land reclamation and land use and the manuring, ecology and survey of grassland. A national soil-survey has already commenced. The Plant Sciences and Crop Husbandry Division will be chiefly concerned with improving the yield and quality of a wide variety of agricultural crops, and will accordingly cater for research in plant breeding, plant pathology, crop protection, entomology, plant introduction (including crops for commercial and other special purposes), plant composition, weed control and general aspects of crop husbandry. The Animal Production Division will cover all phases of animal production from grassland management and feeding to product quality. The work will be organized in the following departments: grassland management, animal husbandry, animal nutrition and biochemistry, physiology, breeding and genetics and meat research. The headquarters of this Division will be at the National Research Centre for Animal Production, at Grange, Dunsany, Co. Meath. A research centre for dairying is being established at

Moore Park, Fermoy, Co Cork, and a sheep research centre at Creagh, Ballinrobe, Co Mayo The Rural Economy Division will include departments of farm management, agricultural economics, agricultural marketing, rural sociology, home economics and agricultural engineering It will provide a service for the economic evaluation of the research in other divisions and for the general management programme of the Institute's farms An agricultural machinery testing service is being organized The horticultural work of the Horticulture and Forestry Division will be carried out at centres dealing with glasshouse and vegetable crops, soft fruits, pomology and bee-keeping A National Research Centre for Glasshouse and Vegetable Crops has been established at Kinsealy, Malahide, Co Dublin In addition, a field experimental station to cater for soft fruits has been set up at Clonroche, Wexford, and an experimental unit for pomology research at Dungarvan, Co Waterford

The foundation ceremony of An Foras Talúntais, commencing with religious services, was held in Dublin on May 19 The opening of the headquarters' offices of An Foras Talúntais at 33 Merrion Road, Ballsbridge, Dublin, by the President of Ireland, and the unveiling of a commemorative plaque acknowledging Unites States aid in the foundation of the Institute, took place in the afternoon

The following officers of the Institute have been appointed

Director Dr. T Walsh

Dr T Walsh graduated in 1937 and was awarded a postgraduate scholarship which he held in the Soil Science Department, University College, Dublin He took the degrees of M Agr Sc in 1938, Ph D in 1940 and D Sc in 1946 on published work He was elected a member of the Royal Irish Academy in 1954 During 1938–45 he was assistant lecturer in soil science, in University College, Dublin, and during 1945–52, soils advisory officer in the Department of Agriculture He was senior inspector in charge of soils and grassland research during 1952–58 In August 1958 he was appointed director of the Agricultural Institute He has represented the Republic of Ireland at many scientific and agricultural conferences and is national representative on a number of committees of the Organization for European Economic Co-operation and the United Nations Food and Agriculture Organization He was responsible for building up research facilities in soils and grassland research in the Department of Agriculture, especially at Johnstown Castle Agricultural College Dr Walsh has specialized in pedology, soil fertility, plant nutrition, and more recently in grassland husbandry with particular reference to the soil fertility – animal nutrition aspects of this subject, and has published some seventy scientific papers

Chief of the Animal Production Division Dr L. B. O'Moore

Dr Laurence Butler O'Moore, who has been appointed chief of the Animal Production Division, took the degrees of M R C V S at the Veterinary College in 1945, M Sc at the University of Dublin for a thesis on the "Physiology of Reproduction" in 1946, and Ph D at the University in 1950 for a study on "Phosphorus Deficiency in Grazing Cattle" Since 1948 he has been on the staff of the Veterinary Research Laboratory, Department of Agriculture, where he held the post of superintending senior research officer with responsibility for research dealing with biochemistry, vaccine production and calf diseases Dr O'Moore is a well-known authority in the fields of animal biochemistry, physiology and nutrition His work on nutritional deficiencies and metabolic disturbances in animals at pasture is especially well known, his reputation in this particular sphere being world-wide

Chief of the Rural Economy Division . Mr J J Byrne

Mr James J Byrne, who has been appointed chief of the Rural Economy Division, was educated at St Kieran's College, Kilkenny, and the National University, and graduated in law, politics and economics in 1940, being awarded a postgraduate scholarship He took the M A (Economics) degree at the National University in 1941, being awarded a travelling studentship with which he proceeded to the University of Cambridge, where he was awarded the M Sc (Economics) degree in 1944, taking the LL B (National University of Ireland) in the same year In 1946, Mr Bryne became lecturer in economics in the University of Dublin, where he was appointed registrar of the Schools of Agriculture and Veterinary Medicine in 1955, and secretary of the Management Committee of the Kells Ingram Farm in 1957 During 1948–54, in addition to his duties in the University of Dublin, he was secretary of the Population Commission, and this work brought him into particularly close touch with the main national social problems Mr Byrne takes up his new post with an international reputation in the sphere of research in economics

BRITISH MAMMALS AND SOME OTHERS

An appreciable number of important papers were produced on a variety of subjects during the conference of the Mammal Society of the British Isles, which was held at Bristol during April 6–9 Miss J Shillito (University of Exeter) described her findings on the population structure, ecology and breeding of the common shrew (*Sorex araneus*) under wild conditions her observations showed much movement of juveniles before their breeding territories were established, the range covered by the males being rather greater than that by the females The various invertebrates consumed by shrews were also examined and listed The other insectivore investigated was the water shrew (*Neomys fodiens bicolor*) P A Jewell and A E Hawkins (Royal Veterinary College) had shown that the normal diet of this shrew had an exceedingly low calorific value, so that the great physical activity employed in the search for food was associated with a resting metabolic rate at least as low as that of a mouse fed on the same standard diet The Earl of Cranbrook pointed out that the saliva of this shrew was probably toxic, since worms bitten by the animal appeared to be paralysed

The food of the water vole (*Arvicola amphibius*), dormouse (*Muscardinus avellanarius*) and harvest mouse (*Micromys minutus*) was discussed by M Knight and their individual preferences noted Small mammals had been studied in the wild in two localities R M Newsom (Bureau of Animal Population) at Wytham had followed the population fluctuations in the bank vole (*Clethrionomys glareolus*), field vole (*Microtus agrestis*) and wood mouse (*Apodemus sylvaticus*) over some sixteen months The results of trapping and marking showed that although breeding of all three species ceased normally during the winter of 1957–58, they all continued to breed in the woodland during the winter of 1958–59 Work on the small mammals of South Rona was carried out by W O Copland and M J Delany (University of Southampton), who trapped for six days during August 1958 Small mammals proved very scarce, and only wood mice (*Apodemus sylvaticus*) and the common and pigmy shrews (*Sorex araneus* and *S minutus*) were found M J Delany had further compared the specific characters in *Apodemus sylvaticus* from the Scottish mainland with large series from Mull and Lewis, and found that these island races only differed from the mainland one in size he therefore concluded that there was no justification for considering *Apodemus hebridensis* as a distinct species With S Krishnaswamy and K A Munday (University of Southampton), he has used filter-paper electrophoresis on blood serum from various murids, and this method has shown that the pattern from the island race of *Apodemus* differs from that of *A sylvaticus* but is closely akin to that of *A flavicollis*

Among larger mammals, J E C Flux (University of Aberdeen) had investigated the colour change in wild specimens of the mountain hare (*Lepus timidus scoticus*) in Aberdeenshire The order in which moulting occurred in different parts of the body was noted and it was found that the spring moult took place much less abruptly than the autumn one G F Moysey showed an electrical device using a spring switch which he had used to obtain automatic records of badgers moving in and out of their setts, preliminary results gave fluctuations in the period of nocturnal activity near and far from the sett, which might be correlated with seasonal changes in badger behaviour

Roe deer (*Capreolus capreolus*) were touched upon by two members D Stephen made observations extending the calving season He also commented upon the absence of the stage of production of buttons by two young bucks kept by him, as a preliminary to the formation of the first antler spikes F J Taylor Page discussed the activity of mature bucks in fraying young trees as a territorial demarcation With T J Pickvance (University of Birmingham), he also described methods of carrying out region mammal surveys, with particular reference to those being carried out at present in the midlands and in Norfolk

The problem of erosion outside Britain was dealt with by H V Thompson, who spoke on the rabbit (*Oryctolagus cuniculus*) in Australia and New Zealand, while O Hook and H N Southern (Bureau of Animal Population) spoke of similar problems caused by the very large number of hippopotami in Uganda Control methods are being used against both these species Other foreign species came under review when Prof K Zimmermann (Berlin) spoke about rodents which he had collected in China, and which in some cases had been brought back alive to Berlin H Bohlken (Kiel) gave an account of his findings on the stomachs of the tylopoda and showed that there were important differences between those of tylopods and ruminants, this suggested that the faculty of rumination differs between these two groups and has been acquired twice over in the phylogenetic history of the artiodactyla

J F D Frazer

STRUCTURAL EFFECTS OF KINETIC HEATING

On April 21 an all-day discussion on "The Structural Effects of Kinetic Heating" was held by the Royal Aeronautical Society at the Institution of Mechanical Engineers

The chair was taken by Mr M B Morgan (deputy director, Royal Aircraft Establishment, Farnborough) In his opening remarks, he said that although the effects of kinetic heating had been pioneered by engine manufacturers, it was a comparatively new field for the structural designer of to-day In the future, kinetic heating effects would have to be taken into account in the design of very high-speed aircraft and missiles, so that the designer would have to become familiar with the scientific background to the problem

The first paper, "Some Factors affecting the Choice of Materials", was read by Mr W G Heath (A V Roe and Co, Ltd) He opened with the assumption that certain fundamental parameters were outside the control of the structures designer The designer must study the effect of these factors on suitable materials, considering not only structural efficiency, stiffness, creep, fatigue and thermal stress but also the availability of the materials and the ability of the workshops to handle them He showed curves giving a comparison of some of the materials available at the present time—aluminium alloys, titanium alloys and steels—which are suitable for structures operating at temperatures up to 500° C Later, brief mention was made of materials suitable for use at higher temperatures He urged every designer to throw away the curves, which he felt sure they all had, of specific strength plotted against temperature, as compression structure efficiency could not be determined from them, and they could be misleading even for tension structures Mr Heath showed curves of 'specific stability' parameters which he had derived He felt that these would be helpful in the choice of the most efficient material for short-life compression structures He stressed the need for more information concerning the effects of creep, fatigue and thermal stress on long-life structures, and the difficulty in obtaining satisfactory experimental results—a point in favour of 'fail-safe' design

He concluded that the final choice of material was strongly linked to the type of structure, and that availability and the workshop processes involved must be considered

During the discussion on this paper a plea was made for some convenient form of presentation of the necessary material properties data for design use, the stiffness and proof stresses in tension and compression would have to be given for each material at a given temperature over varying lengths of time For some of the new materials, which would have to be used for temperatures above 500° C, it was remarkably difficult to discover some of their properties and they were extremely difficult to work with Ultimately, it was the workshops that governed the choice of such materials

A plea was also made for much more compression creep testing to be carried out, which Mr Heath endorsed, saying that he thought the right proportion would be 60 per cent compression and 40 per cent tension testing

Asked for guidance on factors affecting material selection, Mr Heath said that many more materials data were required and suggested that the research activities of universities, technical colleges, etc, in Britain should be co-ordinated

From a structural point of view an opinion was voiced that the general heating problem could be simplified by trying to stop the thermal stresses from arising This could be done by cooling, insulation or other ways of smoothing out the thermal gradients

Dr J S Przemieniecki (Bristol Aircraft, Ltd) presented the next paper, on "The Design of Transparencies" He opened by considering briefly methods of calculating temperature distribution in transparent panels subjected to kinetic heating or cooling, and this led to discussion of the effects of non-uniform temperature distribution, differential expansion and the edge restraint preventing thermal deformations Methods of calculating thermal stresses were suggested, including the concept of 'self-equilibrating' temperature distribution, attention being concentrated on deriving simple engineering formulæ rather than on rigorous mathematical solutions

The choice of design cases for combined pressure and thermal loading was considered and it was shown that, in general, deceleration manœuvres combined with outward pressure constituted the design criteria The effects of various parameters on the magnitude of thermal stresses were analysed and it was shown that for a given material and panel geometry thermal stresses depended mainly on total temperature change, acceleration and the Biot number based on panel thickness Practical design aspects such as choice of material, strength, panel geometry and mounting were also considered Finally, testing of transparencies under pressure and thermal loading was briefly discussed, together with possible methods of strain measurement

During the discussion following this paper it was pointed out that transparencies have two somewhat unfortunate properties they have a very high resistance to heat flow, thus inducing high-temperature gradients and high outer surface temperature, and the radiation effect is small Some reduction of the outer surface temperature and temperature gradients could be effected by the use of double panels with cooling air between them, but it would not be practicable to cool externally the outer surface of the outer panel

Surprise was expressed at Dr Przemieniecki's assumption of zero heat transfer into the cabin It was stated that in fighters a large proportion of the heat entered the cockpit through the transparencies On the suggested method of cooling the inter-space between two panels it was thought to be difficult to get sufficient cooling potential in such a small space Dr Przemieniecki replied that although the assumption of zero heat transfer on the inside surface was an unrealistic case, it could be used effectively for design purposes

Another speaker remarked that the choice of materials for transparencies seemed to be very limited, but he felt that although fused silica had definite merits, toughened soda-lime glass might still be considered favourably for use in civil airliners, where the temperature changes would not be rapid, and where temperatures were not so high that the glass lost its toughening It was suggested to Dr Przemieniecki that the use of transparencies in supersonic aircraft was very limited and that retractable shutters could be a solution Dr Przemieniecki agreed, but thought that the engineering might be too difficult He would prefer to have no windows at all in the passenger cabin and to use closed-circuit television to overcome passenger objections to such a move Shutters could be used perhaps on special-purpose windows

The third paper, "Some Practical Aspects of Kinetic Heating Calculations", was read by Mr C L Bore (Hawker Aircraft, Ltd) He considered some of the practical difficulties encountered when estimating kinetic heating effects for an aeroplane, as distinct from an idealized structure Some of these difficulties arise in the estimation of heat transfer through the boundary layer They may be due to the variations of Mach number and altitude or to the differences between the behaviour of real air and an ideal gas Other difficulties arise from the interacting modes of heat transfer in the interior of a practical structure

He noted that transient temperatures can be found only by means of numerical methods, which have to be very adaptable and not too laborious He outlined methods which have been found suitable for this type of problem and gave some typical results

Interest was expressed in the parameters chosen for presenting the aerodynamic data, but Mr Bore was requested not to ask the aerodynamicists to produce charts showing the values of these parameters over a range of Mach numbers

The final lecture, on "The Advantages and Limitations of the Use of Models", was given by Mr A J Sobey (Royal Aircraft Establishment, Farnborough) He began his discussion on the prospective use of models by distinguishing between the small-scale work-piece used for extensive experiment in order to advance theory, and the replica used in a single representative test to verify design For a structural test evaluation under a realistic thermal field the design of a suitable model was shown to be subject to a series of constraints imposed on the designer by the consistent scaling of essential physical properties

It was shown that scaling of thermal conduction imposed two constraints and internal radiation a third The remaining degree of freedom in choice of scales vanished when the random variation of material properties with temperature forced an identity of temperature scales

The important role of the internal heat transfer process was exemplified in a design study in which some of the relevant parameters were varied and broad conclusions for practical structures were suggested

In the discussion one speaker could not accept the academic idea of infinite accelerations used in the study , but it was agreed that it had a valid application It was thought that Mr Sobey had given a rather depressing picture of the use of models for determining the thermal effects Mr Sobey agreed that models could not be devised to give full representation, but the small-scale work-piece was a useful instrument of scientific research

In bringing the discussion to a close, the chairman remarked on the vital importance of understanding test technique in order to keep ahead of actual aeroplanes, and also noted that there were already numerous aeronautical devices flying successfully while suffering from quite severe kinetic heating effects He concluded by saying that much was known about kinetic heating, but more knowledge was needed in order to refine designs for extreme efficiency

THE MATHEMATICAL ASSOCIATION

THE annual general meeting and conference of the Mathematical Association was held at Southampton during April 8–11 Most meetings were held at the University of Southampton, although the programme included also a civic reception in the Guildhall, visits to a computation laboratory, to a tidal model of Southampton Water and to places of interest in the district

The presidential address, delivered by Prof M H A Newman, was entitled "What is Mathematics ? New Answers to an Old Question" Prof Newman thought it desirable to consider the meaning of mathematics and that the present is a particularly suitable time for such a review There has rarely been a time when the work of mathematicians has been so strongly influenced and directed by their views on the nature of the subject From the revival of mathematics in the sixteenth century until well into the nineteenth century, mathematicians, though they took an interest in logical criticisms of the foundations, did not allow themselves to be deflected by any such criticisms from doing what they pleased

Then, in the latter half of the nineteenth century, there began a more penetrating analysis of the foundations of mathematics than there had ever been before

Soon after the beginning of this century two new and strongly opposed views of the nature of mathematics began to be heard, views which agreed only in their rejection of the interpretation of the logical analysts The 'intuitionist' views of Brouwer had a profound influence on our views about foundations, but had little effect on the direction taken by contemporary mathematics itself The views of Hilbert, on the other hand, have in fifty years led to a transformation of the whole aspect of mathematics Prof Newman said that the introduction of highly organized axiomatic structures has brought extraordinarily rich rewards, in the shape of massive advances, for example, in algebraic geometry of any number of dimensions and in differential geometry, which were entirely beyond the reach of the mathematical methods of even twenty-five years ago

Following these reviews and a consideration of mathematical analysis, Prof Newman asked what bearing these developments have on the problem of showing pupils at school the true nature of mathematics He said that the underlying principle of axiomatic mathematics, namely, that methods of doing things are what most interest mathematicians, or that methods are the heart of mathematics, can have a direct influence on teaching It implies that the meaning and interest of mathematics is to be sought in using and seeing it in action There is no need to make clear the reason for each rule of calculation to the pupil before he starts to use it Mathematics is a language, but it is now generally accepted that children should be taught to talk and read a language before they begin to learn the grammar Boys and men become interested in machinery by seeing it in action and learning to use it Then, if they are of an inquiring turn of mind, they find out how it works If a boy, in the course of learning to use logarithms, gradually learns and understands a coherent body of facts about them, he has learnt some mathematics, even before he finds out that it all depends on indices This, suggested Prof Newman, is the essence of axiomatic mathematics that the systematic development of deductions from abstract laws, and the study of the use that can be made of them, make a branch of mathematics

In another session members heard a vivid description of the Southampton Port Operation and Information Service, with papers by Captain J Andrew, harbour master at Southampton, and Mr A L P Milwright, head of the Ministry of Transport Radar Research Group at the Admiralty Signal and Radar Establishment

Mr Milwright gave a technical description of the radar installation and Captain Andrew explained some of the valuable services that were being rendered in the co-ordination of the movements of shipping

The major session on April 10 was occupied with a discussion of the Association's report, recently published, on mathematics in secondary modern schools

The report is particularly concerned with the mathematical ideas and teaching methods which are considered suitable for the great bulk of the secondary school population between 11 and 15 years of age These children may have shown no earlier sign of readiness for mathematics as an abstract study, or at least have not achieved the attainments in arithmetic traditionally associated with the ablest of their age group There was no intention of offering a specific syllabus of work suited to modern school pupils in general, since circumstances and personal qualities vary so greatly The report does, however, suggest a wide variety of possible approaches to secondary school mathematics, and problems of organization, including syllabus making and the use of examinations, are fully dealt with

The report emphasizes the need for continuity in teaching the subject, and stresses the dependence of work in the secondary school upon that done in the primary school Furthermore, the secondary school is increasingly influenced by the approaching end of full-time schooling and by the demands of adult life as well as those of individual growth and need The pupil's own sense of values is increasingly based on his estimate of what will serve him in good stead in the future, rather than on what will bring him immediate satisfaction and approval The report pays particular attention to the practical topic as a teaching method and to remedial work

During the discussion, Dr J J B Dempster, deputy chief education officer at Southampton, said that greater contact between teachers in secondary modern schools and lecturers in technical colleges was imperative The link between these institutions is tenuous because it is only recently that they have been in contact at all

The stimulus and incentive of a possible future in technical education for the secondary modern school leaver could, however, help to raise the standard of mathematical teaching in the modern schools Dr Dempster believed that concentration on the more able children was necessary, but he hoped that we may ultimately get rid of the attitude that stresses calculations, putting in its place the idea of mathematics as information If pupils could be given a 'revelation', a sudden awareness of what mathematics is about, much of the frustration felt by them and by their teachers might disappear

A description of the *Pegasus* digital computer at the University of Southampton was given by Dr G N Lance, and this was followed by a paper by Dr J P Cleave on the translation of languages by machine Dr Cleave explained that the science of mechanical translation is now well established, particularly in the U S S R , the United States and Great Britain Stimulus to research comes from the presence of vast quantities of foreign technical (legal, economic, scientific, etc) literature, which, through sheer volume, is beyond the capabilities of human translators Human translators are rare, costly and relatively inefficient , they may offer a stylistically polished work but it is often technically inexact The specialist can however, cope well with a crude translation provided the key technical terms are translated exactly Dr Cleave proceeded to show the magnitude of the task, explaining that a programme for mechanical translation must at least contain a dictionary of which a reasonable minimum working capacity is estimated at 10,000 words This requires a reasonably fast access store of at least 20,000 locations, which is several times larger than fast storage devices now available In addition, the programme must include a series of instructions defining the translation operations in terms of shifting and comparison of symbols Inflected languages and compound words, particularly the latter in the German language, also present problems The present development of mechanical translations shows the extent to which the science has already been brought with inadequate equipment When larger-scale storage techniques are perfected, translation will become a practical science

Other papers presented at the conference were on "Plaited Polyhedra" by A R Pargeter, and the "Mechanics of the Fun Fair" by Wing-Commander T R Cave-Browne-Cave

At the business meeting proposals to inaugurate an examination for a diploma in mathematics were welcomed Detailed syllabuses have still to be prepared, but the intention is that teachers (and perhaps others) might obtain a qualification by two years part-time study beyond the advanced level of the General Certificate of Education It is anticipated that the next annual meeting of the Association will establish the diploma, the first examinations for which may be held in 1961

Elected as president for the coming year was Miss L D Adams, a former member of the Schools' Inspectorate Mr F W Kellaway and Miss W A Cooke were re-elected as honorary secretaries, and Prof R L Goodstein as librarian and editor of *The Mathematical Gazette* The new honorary treasurer will be Mr M W Brown, in succession to Mr J B Morgan, who has held office for more than ten years

POSTGRADUATE TRAINING IN THE PUBLIC HEALTH ASPECTS OF NUCLEAR ENERGY

THE existence of many newly developed sources of nuclear radiation, the greatly increased utilization of radioisotopes, and the disposal of radioactive wastes from nuclear fission are factors which constitute a risk not only for those who work with radiation sources and radioactive material but also for the general public The dangers are known and every effort must be made to limit them to the minimum , this will be largely by prevention Workers in public health must, therefore, have appropriate knowledge of those aspects of the nuclear-energy field affecting their own responsibilities, and must be ready, where necessary, to interpret this knowledge to the general public The World Health Organization Committee on Professional and Technical Education of Medical and Auxiliary Personnel was asked to consider the subjects which should be included in the training syllabuses for medical public health officers and other professional public health workers, to determine what degree of knowledge the various members of the public health team should possess, and to indicate suitable methods of providing instruction for personnel who have finished their formal training and are already in service

In the introductory pages of its fourth report* the Committee discusses the problems of measuring radiation and of elucidating its biological effects The public health aspects of peacefully used nuclear energy are then considered in their implications for the community , they are analysed as (*a*) positive aspects (that is, diagnosis, and therapy with radioactive substances , tracer uses of isotopes in biology, medicine, industry and agronomy , food and drug preservation and sterilization) , (*b*) negative aspects (that is, protection from the routine hazards of radiation in medicine and industry , precautions against reactor accidents, disposal of radioactive effluents), and (*c*) public health legislation on the control of such hazards

---

* World Health Organization Technical Report Series No 154 Post-Graduate Training in the Public Health Aspects of Nuclear Energy Fourth Report of the Expert Committee on Professional and Technical Education of Medical and Auxiliary Personnel Pp 53 (Geneva World Health Organization, London H M Stationery Office, 1958) 2 Swiss francs, 3*s* 6*d* , 0 60 dollars

The Committee summarizes the responsibilities, in relation to the use of nuclear energy, of personnel in the various health disciplines—health officers, hospital administrators, industrial hygiene workers, sanitary engineers of all types, veterinary public health workers, and laboratory and other technical personnel, instruction in the field of nuclear energy should speedily be incorporated in graduate and postgraduate courses for public health students The Committee recommends that the teaching content of the courses should cover physical principles, biological principles, the application of nuclear energy and radiation, hazards and protection, each of these subjects is considered at four teaching levels—an orientation course, an introductory course, an advanced course, and a specialist course The compilation of a handbook of radiological health data, to serve as a reference manual for public health workers, was also proposed

RECORDING THE POSITIONS OF MICROSCOPICAL OBJECTS

MORE than a century has elapsed since Maltwood[1] introduced his admirable 'finder', which enabled the user to record the positions of objects on microscopical slides Not many of the original Maltwood finders survive Interest in the subject revived recently, when careful instructions for making similar finders were published[2]

An instrument of the same sort as Maltwood's, but differing in details, has now been put on the market by Graticules Ltd under the name of the 'England Finder' This resembles in appearance an ordinary microscopical slide When it is viewed under a low power of the microscope, it is seen to be divided by rulings into a large number of squares In the centre of each square a circle is inscribed, each circle is distinguished by a letter and a number (for example, *P*31) The part of each square lying outside the circle is divided by vertical and horizontal straight lines into four equal parts, situated north-west, north-east, south-west and south-east of the circle, these are labelled 1, 2, 3 and 4, respectively The letters and numbers are clearly legible

When an interesting object has been found on a microscopical slide, it is brought into the centre of the field of view It is necessary that the slide should lie against the horizontal bar of the mechanical stage, and should be pushed up against the lateral stop The slide is then removed and the finder placed in exactly the same position The finder is examined with a low-power objective If one of the circles covers the centre of the field of view, its letter and number are recorded If one of the corners of a square covers the centre, its number is recorded in addition to the letter and number of the circle enclosed in that square (for example, *P*31/2) One can at any time find the interesting position on the slide by bringing the recorded place on the finder into position and then replacing the finder by the slide

It is claimed by the manufacturers that their finders are all marked in exactly the same way, so that all give the same reading with the same object

Those who have tried both verniers and finders are likely to favour the latter, because the letters and numbers are so easily read, and also because the recorded positions do not relate to one particular microscope only, but are applicable to any instrument provided with a mechanical stage (or some substitute for this) The only disadvantage is that the slide must be removed temporarily while the reading is being made The 'England Finder' can be strongly recommended

VERY LOW-FREQUENCY SPECTRA OF ATMOSPHERICS PROPAGATED THROUGH THE IONOSPHERE

By TATSUZO OBAYASHI

Hiraiso Radio Wave Observatory, Radio Research Laboratories, Nakaminato-shi, Ibaragi-ken, Japan

IT has been known for many years that atmospherics in the very low-frequency band can propagate to great distances In recent years, however, there has been a renewed interest of this problem, many investigators have found an evidence of a pronounced absorption band at 2–4 kc /s, while for frequencies around 10 kc /s there is little attenuation Extensive studies have been made on wave-form characteristics as well as the amplitude frequency spectra of individual atmospherics[1,2] Their results showed distinct frequency spectra of atmospherics, indicating the existence of an appropriate mode of propagation and of the strong selective attenuation due to ionospheric influences A new theory of very low-frequency ionospheric propagation, known as the mode theory, was suggested by Budden[3] in 1951, and further theoretical studies have been pursued, especially by Wait[4,5], who made an elaborate computation on the mode of ionospheric propagation and showed that the characteristics predicted by the theory accord well with the experimental facts

In this investigation, an attempt was made to obtain a more complete experimental proof of the mode theory A new apparatus was developed recording continuously the frequency-spectrum of atmospherics Two sets of radio spectroscopes covering the frequency ranges 1–10 kc /s and 5–70 kc /s were used, each set consisted of the conventional very low-frequencies atmospherics receiver of superheterodyne type, a frequency scanning device with a display unit comprising a cathode-ray oscillograph and a photographic motion camera The bandwidths of the scanner for the two very low-frequency bands were ± 250 c /s and ± 600 c /s, respectively, and its frequency-scanning rate was about 10 c /s Special attention was being paid to obtaining a flat frequency-response of the receiver over the sweep-frequency range and a sharp cut-off for the rest of the frequencies

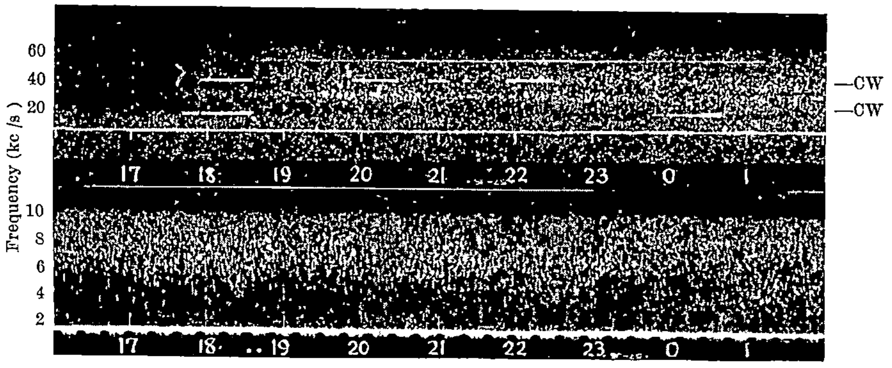

Fig. 1. Frequency spectra of very low-frequency atmospherics. December 14, 1958

The record was calibrated by frequency markers at intervals of 2 kc./s. and 10 kc./s. applied every hour.

Observations of atmospherics using these spectroscopes have been carried out here since June 1958. Simultaneously, the intensity of atmospherics at 27 kc./s. has also been measured continuously. The results so far obtained appear to provide an excellent experimental confirmation of the mode theory.

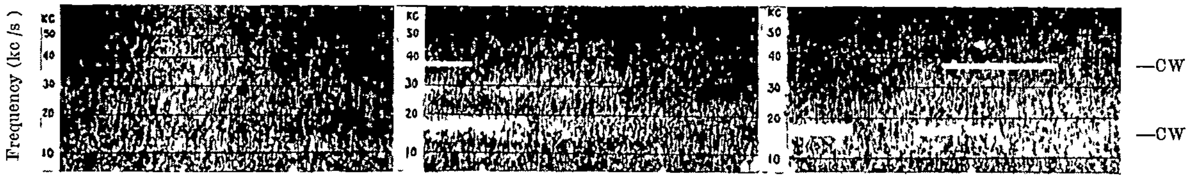
Typical records are reproduced in Fig. 1, in which the light and dark portions indicate intense atmospherics and weak or no atmospherics respectively. Signals from radio stations are also recorded, which appear as white straight lines at, for example, frequencies of 17 and 38 kc./s. It is evident from these records that there exists a frequency-band of strong absorption for atmospherics propagation around 2–4 kc./s. The intensity of atmospherics is maximum at about 10–20 kc./s. and it decreases towards higher frequencies with undulating peaks.

In discussing these frequency-spectra of atmospherics, it must be remembered that the period of sweep frequency (order of 0·1 sec.) is not long enough to cover the whole spectrum of individual atmospherics, which are usually less than a few milliseconds in duration. However, if it is assumed that numerous atmospherics are occurring randomly within a short period of time, a long time-exposure of the film should reveal the relative amplitude-frequency spectrum in a statistical sense.

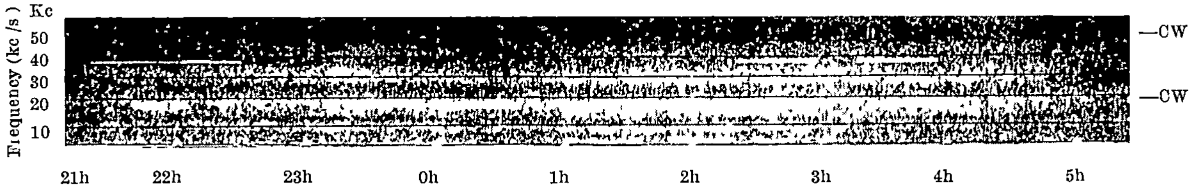
By examining the records, it is found that night-time atmospherics are much less intense and extend to wider frequencies than those of day-time. There exists a strong absorption band at 2–4 kc./s. and certain clear strips of intensity in the higher frequencies, which are changing regularly with the local time. As shown in Fig. 2*a* the short distance atmospherics (probably from sources less than 500 km. distant) do not show such frequency characteristics. Therefore, the general features stated above should be restricted to long distance atmospherics, which may be strongly influenced by the ionospheric conditions. The observed fact that the maximum intensity of atmospherics lies in the frequency range around 10 kc./s. confirms the earlier result, which was based on numerous studies of wave-forms and field intensity measurements of distant atmospherics.

By scanning the film records with a photo-electric scanner, the photographic pattern displayed by intensity-modulated plots was converted to a measure of the amplitude of the atmospherics. Typical amplitude-frequency spectra at night- and day-time are shown in Fig. 3. The night-time spectrum has its maximum at about 8–10 kc./s. and the intensity decreases with frequency in undulating peaks, while the day-time spectrum has a smooth lower maximum at about 15 kc./s. These two types of the spectrum interchange rather distinctly at local sunrise and at sunset. The night-time pattern is shifted towards higher frequencies as shown in Fig. 2*b* although the sunset transition is less clear.

These characteristics of the amplitude-frequency spectrum of atmospherics appear to support the wave-guide mode theory whereby very low-frequency radio waves are propagated to great distances by multiple reflexions in the wave-guide bounded by the Earth and the ionosphere[3,4]. An essential part of this theory is the existence of definite cut-off frequencies in the mode of wave-guide propagation. If we consider space between the ground and ionosphere as a wave-guide, then the cut-off wavelength is given by $2h/n$, where n is the integer specify-



(*a*) Short-distance atmospherics (*b*) Local sunrise (*c*) Solar flare



(*d*) Night-time frequency-spectrum of atmospherics

Fig. 2. Frequency-spectra of very low-frequency atmospherics of ionospheric propagation

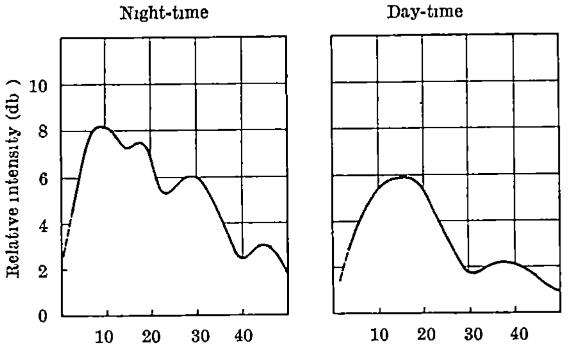


Fig 3 Typical amplitude-frequency spectra of distant atmospherics

ing the number of the mode and h is an effective reflecting height of the ionosphere When the boundary of the wave-guide is not perfectly conducting, as is the case with the actual ionosphere, the cut-off wave-length is not sharply defined and the effective reflecting height of the ionosphere would become higher

From the above consideration, the absorption band observed at 2–4 kc /s may be regarded as the effect due to an ionospheric cut-off of the fundamental mode, as suggested by Budden The dawn effect of the frequency-spectrum, which appears as the shifting of the maximum intensity bands towards higher frequencies, could be explained as the lowering of the ionospheric height or else the increase of the conductivity in the lower ionosphere On the other hand, it is already known from a number of experiments that the reflecting height varies considerably from 90 km at night to 70 km during the day[6] Therefore, this agrees well with the present conclusion

There is an another interesting fact, lending further support to the mode theory This is the relation between the sudden enhancement of atmospherics (SEA), and sudden ionospheric disturbances (SID) An intense solar flare occurred at 13h 35m , August 16, 1958, which was associated with a pronounced sudden enhancement of atmospherics in the record of field intensity of atmospherics at 27 kc /s The record of frequency-spectrum during this period is reproduced in Fig 2c A sudden shift of the frequency-spectrum at the beginning of the solar flare is evident , the band of strong intensity was around 10–20 kc /s up to the beginning of the flare, as is usual in day-time, and then at 13h 35m the band of strong intensity shifted towards higher frequencies of 15–30 kc /s Consequently, at the higher frequencies in the very low-frequency band the intensity of distant atmospherics is enhanced, while at the frequency about 10 kc /s or less a sudden reduction in intensity occurs This confirms the result of Gardner[7] Since it is known that during sudden ionospheric disturbances the electron density in the lower ionosphere is increased and its height is lowered considerably, these facts are consistent with the explanation that the reduction of field intensity in the lower very low-frequency band is caused by the cut-off moving towards slightly higher frequencies, while in the frequencies above the cut-off the intensity is enhanced considerably owing to the good reflexion condition in the lower edge of the ionosphere

COMPARATIVE EFFECTS OF HEAT ON CHROMATOGRAPHY AND ULTRA-VIOLET ABSORPTION OF DEOXYRIBO- OR RIBO-NUCLEIC ACIDS

By Dr SAUL KIT

Department of Biochemistry, University of Texas M D. Anderson Hospital and Tumor Institute, Houston, Texas

THERE is considerable evidence to suggest that the deoxyribonucleic acids (DNA) represent linear, unbranched molecules in which two complementary helical polynucleotide chains are twined around one another[1,2] As proposed by Crick and Watson[3], the two chains are held together by hydrogen bonds between bases, each base being joined to a companion base on the other chain The pairing of bases is specific, adenine going with thymine and guanine with cytosine Lawley[4] has observed that when solutions of deoxyribonucleic acid are heated in neutral saline solution at temperatures of 80° or greater and then cooled to room temperature, the optical density in the ultra-violet is increased by about 30 per cent Table 1 illustrates this effect for various samples of tumour or normal spleen deoxyribonucleic acid In the presence of sodium ions, there is no change in the shape of the absorption curves but the extinction coefficient increases at the wave-lengths 230–280 mμ Since it is unlikely that such treatment breaks phosphodiester bonds, the increased optical density has been attributed to (*a*) the breaking of the hydrogen bonds between pairs of bases and the separation of sections of the two polynucleotide chains , (*b*) a rearrangement of the

Heated 1 hr at 100° at pH 7, 0 01 M or 0 05 M sodium chloride, 0 005 per cent solution of nucleic acid and then cooled to room temperature Optical density read at 258 mμ with Beckman *DK*-2 spectrophotometer more flexible single chains to configurations in which the purine and pyrimidine rings are no longer superimposed[4] The conclusions of Lawley are generally supported by physical chemical studies of solutions of heated deoxyribonucleic acid although the exact results which are obtained depend on the concentration of the acid or ions in the solution[3,5]

The chromatographic profiles on cellulose-anion exchange resins of deoxyribonucleic acid are also markedly modified by brief periods of heat treatment[6] (Fig 1) Most of the heated deoxyribonucleic acid can be eluted from the resins by 0 8 M sodium chloride although higher salt concentrations and increased alkalinity are required for the elution of the untreated samples As the relative ease of elution of mixtures of deoxyribonucleic acid from anion exchangers is in part a function of the molecular weight or state of aggregation of the molecules[7-9] the chromatographic results suggest that molecules of reduced molecular weight are generated as a result of the cycle of heating and cooling

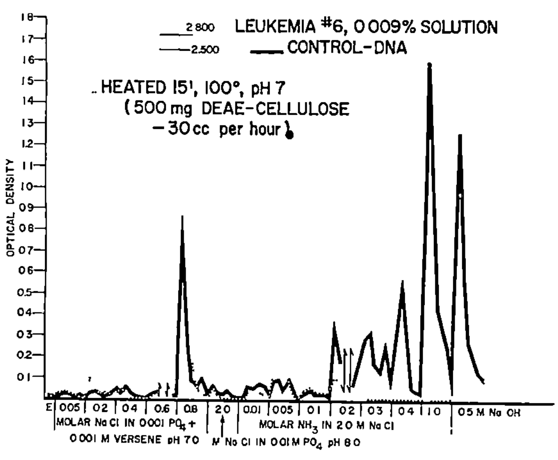

Fig 1 Effect of heat on chromatography of leukæmia No 6 deoxyribonucleic acid Approximately 3 mgm of the acid was applied to each column Recovery of deoxyribonucleic acid on control column, 111 per cent, heated sample, 105 per cent 5 c c aliquots collected, 6 aliquots per eluting solution

Although ribonucleic acids from many sources have been examined by physical methods within the last few years, no clear-cut and consistent picture of the configurational properties has materialized[10,11] It is therefore noteworthy that the effect of heat on the optical density and chromatographic profiles of ribonucleic acid are in marked contradistinction to that of deoxyribonucleic acid

Ribonucleic acid was prepared from the same sources as the samples of deoxyribonucleic acid by modifications of Kirby's method[12,13] The ribonucleic acid was extracted with 8 volumes of 0 01 M sodium chloride and 8 volumes of 90 per cent phenol containing 10 per cent *m*-cresol All operations were carried out in the cold room (about 6°) and the ribonucleic acid was dissolved in 0 01 M sodium chloride rather than water at each of the reprecipitation steps When these samples were heated for 1 hr at about 100°, in neutral saline solutions (0 05–0 5 M sodium chloride) a 20 per cent increase of the optical density was observed (Fig 2) Hall and Doty found a similar increase in the case of calf liver microsomal ribonucleic acid[11] On cooling to room temperature, the optical density is reduced to about 10 per cent above the control value (Table 1) These observations are consistent with the view that intra- and inter-chain attractions in ribonucleic acid arise from hydrogen bonding between purine and pyrimidine bases, but that the fraction of the base pairs involved in hydrogen bonding is relatively unchanged by the heating cycle Indeed, the first heating cycle of freshly prepared ribonucleic acid shows the same results as successive cycles, in contrast with deoxyribonucleic acid, where the optical density never returns to the original value after the first heating[11] Ribonucleic acid which was prepared from a 0 25 M sucrose–0 01 M citrate extract of the tumour cells gave the same results after heating as the total ribonucleic acid of the cells (Table 1)

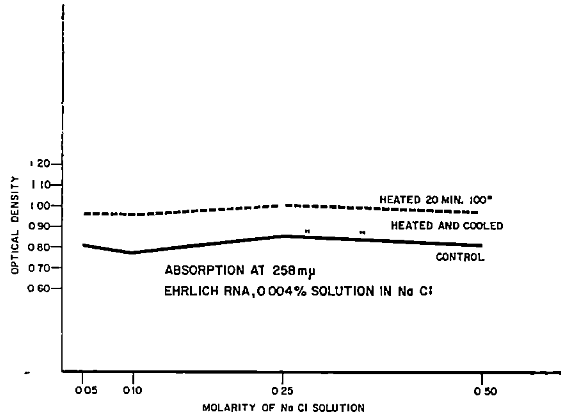

Fig 2 Effect of heating (100° for 20 min) and subsequent cooling to room temperature on the optical density at 258 mμ of Ehrlich ascites tumour ribonucleic acid The acid samples were dissolved in neutral saline solutions (0 05 M–0 5 M sodium chloride) at a concentration of 0 004 per cent ribonucleic acid The Beckman *DK*-2 spectrophotometer was used to record the optical density between 300 and 240 mμ

Preparations of ribonucleic acid have been chromatographed after the samples were heated in neutral salt solution for 15 min at 100° and cooled to room temperature (Fig 3) Again, unlike that of the deoxyribonucleic acid, the chromatographic profiles of the heated ribonucleic acid were unchanged from that of the controls These results add validity to recent suggestions that the ribonucleic acid consists of a single-stranded polynucleotide chain[11,14-16] They are also consistent with the speculative models in which a single-stranded molecule of ribonucleic acid is visualized as functioning in the initial transfer of coded information from double-stranded molecules of deoxyribonucleic acid[17,18]

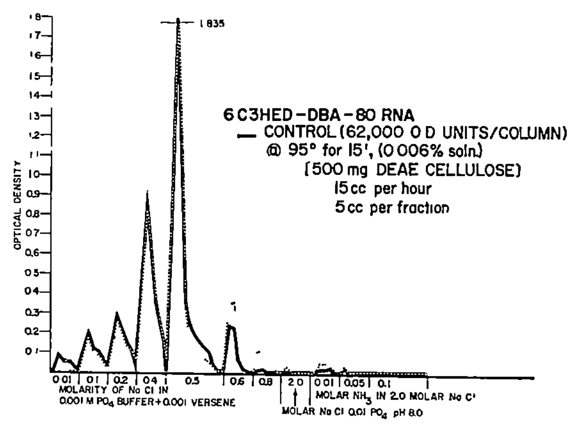

Fig 3 Effect of heat on chromatography of tumour (*6C3HED-DBA*/80)-ribonucleic acid Approximately 3 mgm of the acid were applied to each column Recovery of ribonucleic acid control, 75 per cent, heated sample, 78 per cent

MECHANISM OF THE ATHEROGENIC ACTION OF EXCESS HYDROCORTISONE

By DR HENRY GROSSFELD

Department of Orthopædic Surgery, College of Physicians and Surgeons, Columbia University

IN animal experiments, adrenocortical steroids can act by eliciting vascular damage[1–3] In man, high thereapeutic doses of adrenocortical steroids lead to arteriosclerosis In Cushing's syndrome, excess adrenocortical steroids produce severe arteriosclerosis Other factors possibly involved in atherogenesis, for example, steroid diabetes, and 'stress', show hyperplasia and hyperfunction of the adrenal cortex, and have been assumed to act via the adrenal cortex Therefore, progress achieved in the elucidation of the mechanism of action of adrenocortical steroids might shed new light on problems of atherogenesis

The protein-catabolic effect of C-11-oxygenated steroids, and the stimulation of glyconeogenesis from amino-acids are firmly established results of experiments on animals and man, but no conclusive evidence had been obtained on the question whether glucocorticoids affect the rate of oxidation of glucose On one hand, glucocortical hormone promotes the normal function and survival of the intact cell, as demonstrated by its action on adrenalectomized 'adynamic' animals, and in Addison's disease, but on the other hand, excess glucocorticoid action causes inhibition of growth and of wound healing, and disruption of cellular structure, for example, destruction of lymphatic tissue and of thymus

An investigation into the direct action of glucocorticoids on respiration and aerobic glycolysis of cultured cells has been carried out, in order to obtain more information on the action of cortical steroids on energy production The methods used were described elsewhere[4] In one group of experiments, a single dose of hydrocortisone in high concentration added to a cell suspension in the Warburg vessel before its transfer to the manometric bath caused inhibition of respiration coupled with increase of aerobic glycolysis (Table 1) Hydrocortisone in the same concentration added in a single dose to cultured cells caused growth inhibition averaging 40 per cent for 125

γ/ml, as determined by enumeration of cell nuclei In a second group of experiments, hydrocortisone in concentrations of about 0 50–1 50 γ/ml added to cultures three times at intervals of 2–3 days caused stimulation of respiration (Table 2) The mineralocorticoid deoxycorticosterone showed a considerably smaller effect than hydrocortisone (Fig 1)

These results indicate that hydrocortisone in lower concentrations, by stimulating respiration increases energy production and thus enhances work efficiency In excess hydrocortisone, respiration is depressed, glycolysis increased, and sugar is also synthesized from amino-acids At the same time, inhibition of protein synthesis by excess hydrocortisone may lead to impairment and damage of cellular structure, perhaps by depletion of structural protein In insufficient respiration, hydrocortisone in high concentration appears to be instrumental in causing a shift towards more anaerobic utilization of sugar This would agree with findings of hyperfunction and hypertrophy of the adrenal cortex during strenuous work for which anaerobic energy is utilized[5]

It has been found that fibroblasts derived from various organs produce *in vitro* various patterns of acid mucopolysaccharides[6–8] The chemical differentiation of fibroblasts is maintained for long periods of time only in primary cultures (up to now for more than two years), while replicate cultures of cell strains of mesenchymal origin irreversibly lose the ability to produce mucopolysaccharide Indeed, there is a parallelism between loss of chemical differentiation (that is, production of mucopolysaccharides) and increase of ratio of aerobic glycolysis to respiration[9] It is suggestive that depression of respiration (coupled with release of aerobic glycolysis), leading to loss of differentiation, may be involved in the atherogenic effect of excess hydrocortisone, which has been shown to depress respiration and stimulate anaerobic metabolism In fact, depression of oxidative metabolism in arteriosclerotic[10] and in aged[11] arteries has been reported Depression of respiration, with release of aerobic glycolysis, in addition to vascular damage, could thus be demonstrated in arteries of rats treated with large atherogenic doses of hydrocortisone

Two more diseases of endocrines which normally are involved in carbohydrate metabolism, namely, thyroid and islets of Langerhans, may also become involved in the pathogenesis of arteriosclerosis Myxœdema invariably leads to severe arteriosclerosis There is evidence of increased susceptibility of the thyroid-deficient animal and person to arteriosclerosis In senescent animals, the thyroid is reduced in size[12] Aloxan diabetes leads to arteriosclerosis in rats[13] Diabetes considerably increases the incidence of arteriosclerosis in man A considerable degree of hypertrophy of the adrenal cortex, resembling adenomas in Cushing's syndrome, has been found in diabetic arteriosclerosis[14] The connexion between

* Added to the cultures three times.

depression of respiration and hypersecretion of adrenal cortex can also be seen in the demonstration of increased adrenal weights in rats maintained at a depressed oxygen supply[15].

It has been assumed that glycolysis, *ceteris paribus*, may provide a more adequate environment for fatty acid synthesis than respiration. In fatty acid synthesis, acetyl-S-coenzyme *A* is reduced by reduced diphosphopyridine nucleotide and the reaction products are diphosphopyridine nucleotide, beta-hydroxybutyryl-S-coenzyme *A* and reduced coenzyme *A*. The cycle of reactions is repeated eight times until stearyl-coenzyme *A* is formed. Fatty acid synthesis requires thus the participation of reduced pyridine nucleotide. Since oxidation of lactate is coupled with reduction of diphosphopyridine nucleotide, the ability of lactate to regenerate reduced pyridine nucleotide might be an important factor in stimulating lipogenesis[16,18]. This assumption is compatible with the finding that in tissue-cultured cells in which relatively high glycolysis is a characteristic feature of carbohydrate metabolism, there is a striking tendency to augmentation of cytoplasmic lipid.

Other examples show a relationship between high glycolysis and fatty acid synthesis. Cells in tissue culture exposed to the action of hydrocortisone in *high* concentration show more cytoplasmic lipid than control cultures[19-21]. Large amounts of higher fatty acids, in addition to lactic acid, were found in worms producing about six times more glycogen in fermentation than in respiration[22]. There is a striking accumulation of lipid in the cytoplasm of chondrocytes in cartilage with high rate of glycolysis. It is tempting to correlate the high glycolysis rate found in normal human arteries—51 per cent of total glucose utilization[23]—with the accumulation of lipid in human arteries of healthy individuals of all ages, including infants[24]. It is suggestive that the amount of lipid in arteries increases with the increase of ratio of aerobic glycolysis to respiration.

Several kinds of tissues with predominantly anaerobic metabolism are known, such as, for example, lens, cartilage, human sperm, intestinal mucosa. Other tissues, such as heart muscle, have an almost exclusively oxidative metabolism. Still other tissues, for example, testis, brain, medulla of kidneys, pituitary, arteries, possess both respiratory and fermentative systems[25]. They possess a regulative device which enables them to use either their anaerobic or their aerobic system. They are equipped with a switch mechanism (their 'Pasteur effect') which keeps fermentation from functioning so long as the respiratory system supplies sufficient energy, but may throw it into operation in emergency when energy supply from respiration is either blocked or is too slow. It has been presumed that hormonal action might be involved in such regulations[25]. Muscles suddenly put under strain must rely predominantly on a supply of anaerobic energy[25,26], and there is no basic difference in energy metabolism between striated and smooth muscles[28]. There are indications that adrenocortical steroids may be instrumental in the switch from oxidative to fermentative metabolism[27]. Anaerobic glucose utilization was found to be, to a significant extent, the source of energy for the work of arteries[23]. It is suggestive that the ratio of aerobic glycolysis to respiration in arteries depends on the extent of blood flow needed for the organ supplied by the arteries, and on the oxygen tension of the blood.

Let us consider as an example the coronary arteries of the heart. The metabolism of the heart muscle is strictly oxidative. Of the total myocardial oxygen used, 16 per cent is for glucose oxidation, 17 per cent for lactate oxidation and 67 per cent for oxidation of fatty acids which are derived from blood lipids[29]. Alimentary lipæmia would result in an increase in the contribution of fatty acids to the oxygen consumption of the heart. The oxygen extraction of the heart muscle is maximal. Therefore, the response of the heart to increased demands of oxygen must consist in an increase of coronary blood flow. The response to anoxia with lactic acid production in the heart muscle is obtained only in its severest forms, for example, in hæmorrhagic shock, or ventricular fibrillation. An increase of oxygen demand during exercise necessitates an increase of coronary blood flow, which in part must be carried out by increased work of the coronary arteries. This additional work of the arteries requires an additional supply of energy. The source of such additional energy cannot be aerobic since it is designed to make possible production of aerobic energy by increased blood flow. (Blood flow through the vasa vasorum also depends on heart muscle work.)

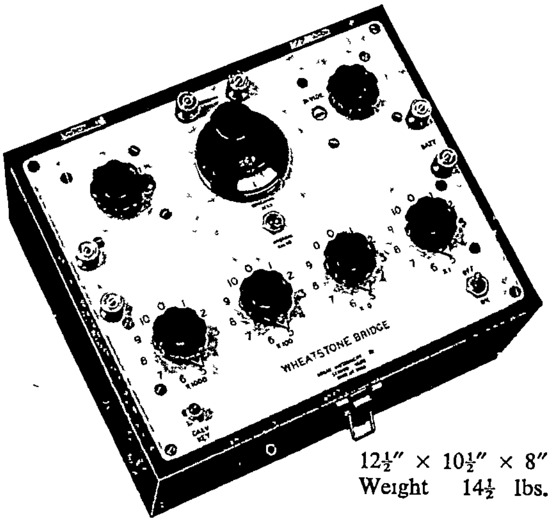
It must thus be postulated that the coronary arteries are able to increase the utilization of anaerobic energy when increased flow to the heart muscle is required for the supply of more oxygen. In fact, as has recently been found[23], anaerobic energy accounts for 51 per cent of the total energy production in arteries. It is suggestive that the extent of anaerobic energy production in the coronaries increases in proportion to the extent of relative hypoxia. It would appear that so long as the ratio of anaerobic to aerobic metabolism is not too high, their work remains unimpaired. But if certain as yet unidentified steps of oxidative metabolism are permanently depressed, anaerobic metabolism becomes the main source of energy supply, which is less economical and in some respects inferior to the normal arterial metabolism. It may perhaps give rise to increased formation of cytoplasmic lipid. It might eventually impair the functional and structural cellular integrity[30,31]. In that regard, the following possibilities should be considered. Cell differentiation presumably requires the presence of intact organized respiratory enzyme systems. When cells normally deriving part of their energy from oxidation are forced by environmental conditions, such as relative hypoxia or by damage to certain enzymes, to use anaerobic energy only, pathological alterations may eventually result. Increased anaerobic metabolism in the coronaries, stimulated by excess hydrocortisone, is associated with excessive proteolysis, which may cause depletion of functional protein and interfere with re-synthesis of enzyme systems. Extensive depletion of storage and of functional protein under the influence of excess hydrocortisone has been reported[5].

These general concepts, which have evolved in the course of experimental work, were conceived only as a tentative approach to some problems of atherogenesis. They are not new, since they were anticipated in 1876 by Louis Pasteur. The basic difference between respiration and fermentation as expressed in cell morphology and the efficiency of performance of specific cell functions was noted by Pasteur when he described his famous observations as follows: "In the absence of air, yeast cells deteriorate, become granular, form proturbances which disintegrate, and eventually degenerate. Addition of a small quantity

DORAN

Self-contained Wheatstone Bridge

Cat. No. E.3378.



12½″ × 10½″ × 8″
Weight 14½ lbs.

The instrument illustrated comprises four decade resistance units totalling 11,110 ohms with ratio arms to cover a range of measurement of from 0 01 ohm to 10 megohms The galvanometer provided has ample sensitivity for the greater part of the range, but terminals with change-over switch enable an external galvanometer to be employed for more precise work.

Further details of this and a precision type bridge will be found in List 108A

Rašková Helena,

PHARMACOLOGY OF SOME TOXINS

1958 – L 8° – 134 pp – 71 illus – 4 suppl on art paper – 9 tables – h c $3 10

This treatise summarises the results of many years' work on the effects of some toxins on different activities of organisms of the human body and certain special methods of cures The work is supplemented by references to literature and by a great number of illustrations The monograph, published in English, will be a welcome guide for scientists, pharmacologists and also an aid in clinical practice

Philipp Maximilian Opiz und seine Bedeutung fur die Pflanzentaxonomie

(Philipp Maximilian Opiz and his Contribution to Plant Taxonomy)

1958 – L 8° – 272 pp – 20 illus – (G) – h c $2 20

This volume presents the life-work of the Czech botanist P M Opiz, who exerted a strong influence not only on Czech science, but upon whose views the Vienna school letter drew The symposium, written in German, was published on the occasion of the hundredth anniversary of his death Compilers Academician Bohumil Němec, Dr Ivan Klášterský, Dr Miloš Deyl, Dr Mirko Svrček, Josef Holub, Dr Emil Hadač, Ferdinand Weber

Komárek Jiří – Ettl Hanuš,

ALGOLOGISCHE STUDIEN

(Algological Studies)

1958 – L 8° – 358 pp – 46 illus – XII suppl on art paper – h c $5 80

The book discusses Cyanophyceae and some groups of green algae It evaluates taxonomically various species according to new taxonomic marks The book is written in German

An Introduction to Mathematics for Students of Economics

J PARRY LEWIS

For economics students whose mathematics were abandoned at an early age, this book revises elementary algebra and introduces the necessary trigonometry and co-ordinate geometry before proceeding to a longer treatment of calculus The author guides the reader through the processes of differentiation and integration exponentials, and problems of maxima and minima of functions of one independent variable, before introducing functions of many variables and such topics as Lagrange multipliers *With diagrams 40s*

Nuclear Reactor Physics

RAYMOND L MURRAY

A logical and straightforward introduction to the methods of analysis of reactor design with many numerical examples drawn from practical situations in the reactor field The main emphasis throughout the text is on the distribution in energy and space of neutron flux, the determination of the critical amount of fissionable material, and the transient behaviour and control of the reactor as a source of heat *Diagrams 30s*

MACMILLAN BOOKS

Matter, Earth and Sky

GEORGE GAMOW

This lively book by the Professor of Physics at the University of Colorado deals with physics, chemistry, astronomy, geology, and meteorology, under three heads Matter and Energy, Microcosm and Macrocosm *Well illustrated 50s*

Practical Invertebrate Anatomy

Second Edition *W S BULLOUGH*

In this edition, Professor Bullough has provided a series of brief, practical descriptions of the structure of more than a hundred invertebrate animals commonly examined or dissected by advanced students of zoology 'The value of this standard work is emphasized by the need for a second edition within eight years'—*Biology and Human Affairs* *With diagrams 30s*

NEW **McGraw-Hill** BOOKS

KERR **Optical Mineralogy**

This well-established textbook, formerly written by Rogers and Kerr, has now been thoroughly revised and brought up to date It explains the use of the polarizing microscope in the study of transparent minerals, and is equally useful for university students and research workers in ceramics, chemicals, petroleum, or soil analysis The improvements in this revision include a rearrangement of the descriptions of minerals to emphasize group relationships, a new chapter on the universal stage, new material on optical data, revised identification tables, and many new illustrations 66s

KRAUSKOPF **Fundamentals of Physical Science fourth edition**

Here is a substantial revision of a well-known textbook on general physical science Presenting the subject as a unified field of knowledge, it emphasizes the inter-relationships of the separate sciences rather than the artificial divisions between them Science is treated not as a set of facts to be learned, but as a living, growing field of intellectual adventure and practical accomplishment Material is taken from astronomy, chemistry, physics, and geology, but no attempt is made to provide superficial 'complete' coverage 54s

STERNBERG and NEWCOMER

Modern Dermatologic Therapy

This book presents recent research and developments in the world of dermatology, and closely allied fields, and gives special emphasis on their influence on currently accepted methods of treatment This book is unique in its field, in that the Editors have brought together 21 contributing specialists with a wide experience, thus providing authoritative coverage of the specific topics presented 77s 6d

STEWARD and FARON **Native Peoples of South America**

Two noted anthropologists have written this cultural-historical description of the South American Indians from their first appearance in South America to the present time The aim is to present why and how the different varieties of culture developed in pre-Columbian times, and, under Western influences, in post-Columbian times 66s

WHITE, HANDLER, SMITH, and STETTEN

Principles of Biochemistry second edition

The revised edition of this most successful textbook in biochemistry continues to stress the fundamental principles and concepts of the subject, considering where possible the mechanisms of, and factors influencing, biological reactions Changes have been made in the text following recent rapid advances in the knowledge of the subject, with special emphasis given to metabolism, endocrinology, biochemical cytology, and the specificity of enzymes A particularly useful book for chemistry graduates, and medical and dental students £5 16s 6d

Brewster and the labours of philosophers

'The result of this experiment presented me with a phenomenon so extraordinary in its aspect . . . and lying so close to the root of atomical science, that I am persuaded it will open up a field of research which will exhaust the labours of philosophers for centuries to come.' The experiment, in 1832, had led Sir David Brewster to conclude that 'the original light of the sun is continuous from one end of the visible spectrum to the other and that the deficient rays are absorbed by the gases generated during the combustion by which the light is produced.' The philosophers have laboured to good effect, and their endeavours have led in our day to automatic spectrochemical analysis—the quickest, surest, most comprehensive, and most economical method of analysis in research and industry, and one for which we are selling instruments to progressive firms throughout the world.

OPTICAL ACTIVITY OF STERCOBILIN AND *d*-UROBILIN

By Prof C H GRAY, P M. JONES, Dr W KLYNE and Dr D C NICHOLSON

Departments of Chemical Pathology at King's College Hospital Medical School, London, S E 5, and at the Post-graduate Medical School, Hammersmith, London, W 12

THE identification of the structural factors responsible for the optical activity of the urobilinoid pigments presents an interesting problem in stereoisomerism Some properties of the five pigments at present known are summarized in Table 1 , their structures are shown in Fig 1 Laevo-rotatory enantiomorphs of *d*-urobilin and *d*-urobilin IXα, which are present in the racemic forms of these pigments, have not yet been isolated (The use of the prefix *d*- to indicate a dextro-rotatory compound is now contrary to standard practice in organic chemistry ; it has, however, become customary in this particular field)

Although the molecular structures of stercobilin and *d*-urobilin are known[8], their stereochemistry and the origin of their optical activity remain obscure Optical activity might conceivably arise from nonplanarity of the system of four pyrrole nuclei , this possibility can, however, be excluded since biliverdin and bilirubin, which have no asymmetric carbon atoms, are not optically active Asymmetric carbon atoms are present in one α-position of each of the terminal pyrrolidone rings (in stercobilin) and pyrrolinone rings (in *d*-urobilin) , in stercobilin there are also asymmetric carbon atoms in the β-positions of the end rings Urobilin IXα may then be either a racemic *d*-urobilin IXα or a meso-like compound in which the two asymmetric carbon atoms exert opposite effects

Stercobilin retains its optical activity even on treatment with warm potassium *t*-butoxide, while *d*-urobilin is rapidly racemized in 1 25 *N* aqueous

Table 1*

Pigment	Source	Molecular formula	λ_{max} for solution of hydrochloride in $CHCl_3$†	$[M]_D$ for hydrochloride in $CHCl_3$
Stercobilin	Human fæces (1) and urine (2)	$C_{33}H_{46}O_6N_4$ (3)	496–498 [8 75 × 10^4] (4)	− 24 × 10^3 (5)
d-Urobilin	Human fæces (5) after antibiotic therapy and in biliary infection (6)	$C_{33}H_{40}O_6N_4$ (7)	499 [8 5 × 10^4] (4)	+ 29 × 10^3 (5)
Racemic *d*-urobilin	*d*-Urobilin by treatment with alkali (8)	$C_{33}H_{40}O_6N_4$ (assumed)	499 (4)	Inactive (8)
Urobilin-IXα	Probably human (9) fæces, synthesis (10) and *in vitro* dehydrogenation of mesobilirubinogen (11)	$C_{33}H_{42}O_6N_4$ (12)	496–497 (4)	Inactive
d-Urobilin IXα	Tetrahydro-*d*-urobilin by dehydrogenation (8)	$C_{33}H_{42}O_6N_4$ (assumed)	499 (4)	+ 29 × 10^3 (8)

* Figures in parentheses are reference numbers.

† Figures in square brackets are extinction coefficients

alkali at room temperature This difference between the two pigments may be explained by the effect of the extra unsaturation in facilitating the ionization of the hydrogen atom bound to the asymmetric carbon atom in *d*-urobilin Examples of simple optically active pyrrolidone compounds with one asymmetric carbon atom are 5-carboxypyrrolid-2-one (pyroglutamic acid) and its ethyl ester[14], which resemble the end rings of stercobilin without the β-substituents The possibility of optical contribution by other structural features in the urobilins is being explored

The large molecular rotations of the urobilinoid pigments[15,16] at the sodium *D*-line (589 mμ) are a consequence of the fact that their absorption bands (~ 500 mμ) are close to this line The availability of a spectropolarimeter[17] led us to measure optical rotatory dispersion curves for stercobilin and *d*-urobilin (Fig 2) from 620–470 mμ These curves show that the antipodal relationship of the rotations of these two pigments is more extensive than is evident from their effects solely on sodium light The typical 'Cotton effect' curves[18], with marked changes in optical rotation near the absorption maximum, show that the groups responsible for light absorption also affect rotation[19,20] The dipyrrylmethene group which is responsible for the main spectral absorption band of the urobilins[21,22] must also, therefore, be chiefly responsible for their optical activity at about 500 mμ Further work on other derivatives is in progress

It is interesting to note that in stercobilin the two centres of asymmetry adjacent to the dipyrrylmethene (DPM) groups are each attached to H, NH, CH$_2$—DPM, and a saturated alkyl group, here the amplitude[18] of the Cotton effect is moderate (~ 130 × 10^3) In *d*-urobilin, on the other hand, the centres of asymmetry are attached to H, N, CH$_2$—DPM and a conjugated, unsaturated system, the amplitude here is much greater (~ 300 × 10^3)

ADAPTATION OF A LEAD-TOLERANT POPULATION OF *AGROSTIS TENUIS* TO LOW SOIL FERTILITY

By D. JOWETT

University College of North Wales, Bangor

ATTENTION has recently been directed[1] to populations within *Festuca ovina* and *Trifolium repens* adapted to different levels of soil calcium In the same publication the authors reported failure to find similar differentiation within *Agrostis tenuis* However, further work indicates that such differentiation does exist within this species

A population of *A tenuis* growing on lead-ore grindings at Gogınan (Cards) has already been shown to be tolerant of lead[2,3] However, in addition to being rich in lead the soil is of very low fertility Soil analysis by extracting with $N/2$ acetic acid gives the following values per 100 gm soil

Lead 7 1 m equiv , calcium 0 15 m equiv , phosphorus pentoxide 1 2 mgm

The growth of this population in relation to different mineral levels has therefore been investigated in sand culture, by a technique previously described[4] It was compared with a non-tolerant population from a nearby pasture The results of one such experiment are shown in Tables 1 and 2 This was designed as a factorial experiment with four levels of calcium and three of phosphate, but there was no significant interaction between the two nutrients

It is apparent that the pasture population responds to calcium and phosphate within these limits, whereas the lead mine population shows no response to calcium and a lesser response to phosphate However, in both cases the major part of the response is shown between the two lowest levels Therefore two further experiments were set up, the results of which are shown in Tables 3 and 4

Despite the rather erratic results for the lead mine population the general trends are the same as before The major response to calcium in the lead mine population occurs up to 4 p p m , whereas the pasture population increases in yield up to 10 p p m In the case of phosphate, the populations yield similarly at 2 and 4 p p m but diverge thereafter Calculation of linear regressions of yield on log nutrient concentration gives a good fit and high significance (0 01 per cent) for both nutrients in the case of the pasture population, but no significance and very poor fit for the lead mine population The differences between the two coefficients are not significant largely owing to the high error variance of the lead mine population This high variance may be explained if the population consists of a diverse collection of genotypes, the major unifying feature being the possession of lead tolerance Greater replication is desirable

Table 1 CALCIUM (DRY WEIGHT YIELD, GM)

Population	Calcium p p m			
	5	15	50	200
Lead mine	53 21	50 51	50 24	47 45
Pasture	53 42	77 65	70 43	58 94

S E = 7 75

Table 2 PHOSPHATE (DRY WEIGHT YIELD, GM)

Population	Phosphorus p p m		
	5	25	125
Lead mine	52 89	74 74	73 78
Pasture	66 80	93 22	100 42

S E = 9 02

Table 3 CALCIUM (DRY WEIGHT YIELD, GM)

Population	Calcium p p m				
	2	3	4	6	10
Lead mine	10 48	13 31	22 67	12 41	18 03
Pasture	13 35	15 79	16 01	19 52	27 91

S E = 3 90

Table 4 PHOSPHATE (DRY WEIGHT YIELD, GM)

Population	Phosphorus p p m				
	2	4	8	16	32
Lead mine	10 28	15 54	11 09	18 03	16 13
Pasture	10 99	16 66	21 87	20 99	26 87

S E = 3 70

The results indicate that the lead mine population is adapted to low levels of calcium and phosphate Walker *et al* [5] found similar adaptation in serpentine endemic species , but in their case high magnesium accompanied low calcium-levels The situation on lead mines is in many ways similar to that on serpentine, except that magnesium is not present in quantity However, here the differentiation is within a single species and not between species

Previous failure to find such differentiation within *A tenuis* may have been due to failure to find sufficiently severe habitats In more normal habitats *A tenuis* tends to be replaced by *A canina* at low fertility-levels, but in lead mine habitats this is not so As a result, *A tenuis* is here subject to the most extreme conditions of low fertility

A considerable range of adaptation to soil mineral-levels has now been found in this species It has populations tolerant of lead, copper and nickel poisoning, and of low levels of calcium and phosphate Either it is remarkable in this respect, or such variation is much commoner than previously reported The fact that both species previously examined in this Department showed similar variation suggests the latter to be the case

Deposition of Trace Elements in Basic Magma

Perhaps the most detailed investigation of the fractionation of trace elements during the deposition of a mineral is that carried out on the basic magma of the Skaergaard intrusion[1]. We will consider the formation from the melt of the solid silicate phase of this magma, examining the inclusion of trace elements. The time sequence of the solidification is fairly well established[1]. Thus the deposition of the trace elements can be followed as a function of the percentage, X, of the solid phase formed. This is done in Figs. 1 and 2, where R gives the ratio of the concentration of the element in the liquid after X per cent solidification to the concentration in the initial liquid. A downward curvature to a line represents preferential removal of the element or a partition coefficient of that element favouring the solid rather than the liquid. The orders of deposition are

$Ni^{II} > Co^{II} > Fe^{II}$, $Ni^{II} > Cu^{II}$, and
$Cr^{III} > V^{III} > Sc^{III} > Ga^{III} > Fe^{III}$

I offer the following explanation of these orders.

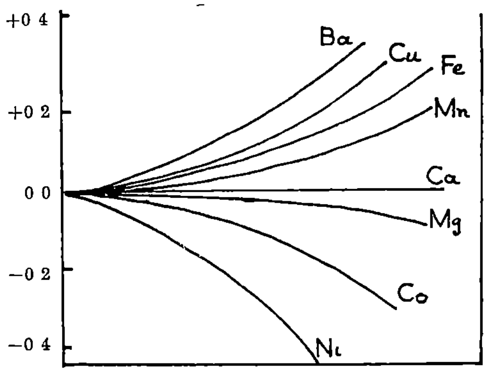

Fig. 1. The uptake of divalent cations into the silicate

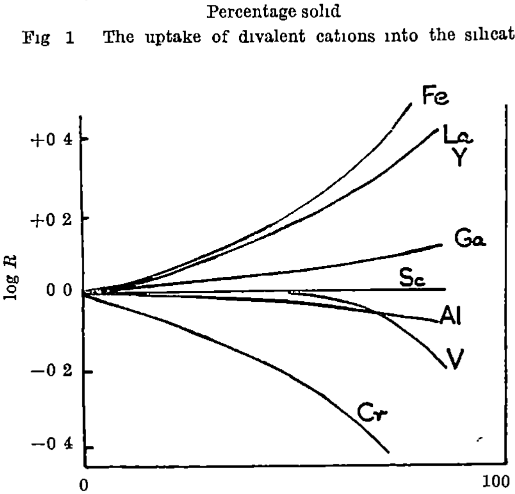

Fig. 2. The uptake of trivalent cations into the silicate

The process of the uptake of an ion into a crystal from a melt can be thought of as being characterized by (1) an increase in average co-ordination number to a fixed value for all the atoms, and (2) a decrease of the interatomic distances. The two terms are consistent with a greater bond energy, lower heat content, on formation of the solid phase. This is generally observed. The change in heat content can be further analysed. An element which is particularly stabilized in a given co-ordination site, say, in an octahedral hole, will be expected to gain greatly in stability on passing from a melt of irregular co-ordination number to a regular solid which provides such an octahedral hole. Again, ions which have large energies of polarization will gain in energy considerably on transfer from the liquid to the solid phase due to the shortening of interatomic distances. Polarization energies are very dependent upon these distances. Now it is well established that the polarization energies of d electrons are important in the stabilization of transition metal ions in certain symmetry positions, co-ordination spheres, rather than in others[2]. In an octahedral site these polarization energies are in the orders

$Ni^{II} > Co^{II} > Fe^{II} > Mn^{II} \gg Ca^{II}$, $Ni^{II} > Cu^{II} > Zn^{II}$
and $Cr^{III} > V^{III} > Sc^{III} = Ga^{III} = Fe^{III}$

These orders are almost exactly those found for the selective uptake of the ions into the Skaergaard intrusion silicates. The above ions normally go into octahedral holes in such minerals as these silicates. We conclude that selective uptake is based upon polarization energies which are highly dependent upon hole symmetry and interatomic distances. We expect that the same trace elements will be accumulated preferentially in silicates generally. This might explain the absence of nickel and chromium in biological systems. In minerals such as sulphides, the polarization will be different in origin and copper will be preferentially absorbed. In minerals providing holes of quite other symmetry, the order of uptake will be different again.

I wish to thank Prof. L. R. Wager, Prof. L. H. Ahrens and Dr. E. A. Vincent for their help.

Origin of the Worzel Deep-Sea Ash

In a recent paper[1], Worzel announced the discovery of an extensive ash deposit at the bottom of the Pacific Ocean. Ewing, Heezen and Ericson[2] have suggested in a companion paper that the deposit may well be of world-wide extent. If this should prove to be the case, the origin of the Worzel ash layer becomes a matter of extraordinary interest. The mass of a world-wide layer would be of the order of 1×10^{20} gm., which exceeds by a factor of ~ 300 the yield of the largest volcanic eruption recorded during historic times[3] (Tambora, 1815)

Moreover, the areal distribution of volcanic ash is usually quite limited[2]. Worzel and Ewing *et al.* have therefore proposed the following events as possible sources of the ash: a single very large volcanic explosion, the simultaneous explosion of many volcanoes, a cometary collision, or some other catastrophic event involving bodies of cosmic origin.

From the data of Öpik[3] one finds that a particle-size distribution peaking in the fractional mm. range, as observed for Worzel's ash, could indeed be obtained by ablation of mm.- to cm.-sized particles. However, a cometary or asteroidal origin of the ash is unlikely for a number of reasons. If the break-up were to occur at a distance from the Earth that was large compared with the distance to the Moon, only a very minute fraction of the debris would be swept up by the Earth, so that the mass of the disrupted body would have to be many orders of magnitude greater than 10^{20} gm., that is, far in excess of the masses of comets or asteroids. Moreover, the residence time of interplanetary debris is of the order of 10^6–10^9 years, as indicated by the cosmic-ray ages of meteorites[4,5], and Öpik's calculations[6], whereas the deposition of the Worzel ash took place within no more than a few years. Further, it is unlikely that a mass of the order of 10^{20} gm. can be accounted for even by means of a direct hit by a comet or asteroid. Although gravitational tests have only yielded an upper limit of $\sim 10^{24}$ gm. on the masses of comets, several other independent arguments indicate that the mass of a reasonably large comet (Halley's comet) is about 3×10^{19} gm. The masses of the more typical comets are probably significantly lower than this. Asteroids of the required mass do exist but are unlikely to be found so far outside the asteroidal belt. Finally, although its chemical composition has not yet been determined, the ash is quite unlike meteoritic[2], cometary, or asteroidal matter, as indicated by its low density and refractive index (2.38 and 1.500, respectively), its low nickel content ($\leqslant 0.01$ per cent.; spectrochemical analysis by Dr. A. Du Fresne), and its glassy character. These properties are much more reminiscent of terrestrial crustal material (for example, volcanic ash), which is high in silicon, calcium, aluminium, sodium and potassium, and low in magnesium, iron and nickel relative to undifferentiated meteoritic matter. The resemblance to volcanic ash has been pointed out by Ewing *et al.*[2]

Two other cosmic sources might be considered: galactic dust clouds and the Moon. A simple calculation shows that passage through a galactic dust cloud of some two solar masses would enable the Earth to pick up a 10-cm. layer of non-volatile matter. However, if the pick-up is to be complete within a short time, say 10 years, the cloud must have had the unreasonably high density of 10^{-11} gm./cm.^{3}. The only known, non-stellar objects in space that may have densities of the right order of magnitude are the so-called 'globules' (believed by some to be proto-stars in an early stage of gravitational contraction). The probability of encountering such an object is exceedingly small; moreover, any reasonable distribution of particle sizes within the globule would contain enough grains in the range of maximum light absorption (that is, $\sim 0.5\mu$) to black out completely the Sun, with calamitous effects on terrestrial life. Finally, the near-passage of a massive cloud would perturb the planets, destroying the regularity of their orbits, and would almost certainly sweep the comets from the solar system.

A catastrophic event within the Earth–Moon system, for example the collision of a giant meteorite with the Moon, cannot be ruled out on grounds of chemical composition. The composition of the Moon's crust is not known; but in the light of recent work on mineral differentiation in small bodies[7], there is no *a priori* reason why it should not be differentiated to a degree close to that of the Earth's crust or Worzel's ash. However, it can be shown that a meteoritic impact of the kind that gave rise to the lunar craters cannot eject enough material to account for the collection of 10^{20} gm. by the Earth. The mass deficit of the very largest craters may barely approach this value, but even under the most favourable conditions scarcely more than a few per cent of the ejected matter will reach the Earth within the required few years.

It appears that an extra-terrestrial origin of Worzel's ash is highly improbable. Yet its world-wide distribution, if demonstrated to be true, will be difficult to explain even in terms of a terrestrial origin. Data on the dispersal of H-bomb debris and volcanic ash indicate that the distribution of particles in the 70–200μ range is limited to distances of the order of 10^3 km. or less. It will be of interest to establish its origin in a single event by chemical analysis of samples from widely scattered locations.

A volcanic eruption of this magnitude should have at least two other observable effects. It would carry enough μ-sized dust particles into the stratosphere to reduce the amount of sunlight reaching the Earth, possibly enough to initiate a period of glaciation. This possibility has been independently suggested by Dr. Bruce C. Heezen (private communication). A palæotemperature measurement of material immediately above and below the Worzel layer may provide a clue in this respect. Furthermore, the mass deficit at the eruption site would produce a negative gravity anomaly that may not yet have been completely obliterated by isostatic equilibrium.

This work was supported in part by the U.S. Atomic Energy Commission.

Wear Observations through Interfacial Micro-Windows

DIRECT observations of wearing processes are generally obscured completely by the slider or bearing material. As a result, a good deal of speculation has accumulated concerning the unknown mechanisms of wear. With reference to graphite, no satisfactory understanding had been gained.

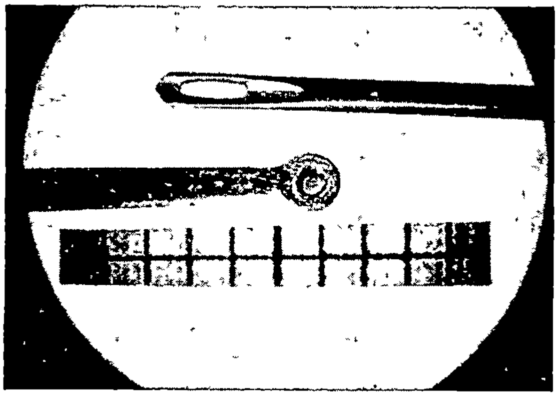

Fig. 1. Diamond micro-window in mounting, with fine needle and metric strip (× 6)

In a recent micrographic study of wear[1] upon graphite it was shown that the wearing process could be studied more directly by arranging a sliding contact under a microscope and following the detailed processes. The observations were further simplified by using single oriented crystals for the surfaces undergoing the wear. With selected adjustments of the illumination a good deal of new information was revealed.

An obstacle in this micrographic technique was that the slider or micro-probe was opaque and hid the contact site from view. Only surrounding effects were visible. In continuation it was found that the slider may be a thin transparent body which then serves as a micro-window. Then the real interface of the contact may be focused upon directly at high magnification.

Small glass lenses as sliders were first tried. A plano-convex lens was mounted at the end of a needle in a micro-manipulator and was pressed against graphite or molybdenite crystals having flat areas. The well-known Newton's interference fringes which were produced over the small air gaps indicated at once the topography of the surfaces, in respect to elevations and actual zone of contact.

Upon sliding the glass over a crystal surface, the details of the wearing process were directly observed, including the variations of contact position, the influence of single asperities and of particles on the friction and wear, the geometrical nature of the wear removal process, and the surface adhesion.

As a further step, a diamond micro-window has been machined for this study. This provides a hard transparent carbon tool of known geometry to slide against a plane graphitic carbon surface. This diamond lies completely within the field of view at magnification of 320, and hence all contact areas may be seen at once. It is smaller than a fine needle's eye (Fig. 1) with a maximum diameter of 0.94 mm and thickness of 0.66 mm. It is optically flat on the upper surface, facing the microscope objective, and slightly convex on the sliding surface, but optically smooth. As a sliding window, it shows a detailed picture of surface interactions upon its face during sliding, as well as the topography from the Fizeau fringe patterns.

The technique described makes it possible to view surfaces as they are brought into contact at magnifications large enough to yield significant results, to observe the subsequent damage to the sliding surfaces as it occurs, and to measure the contributions of individual asperities to the friction.

I wish to thank E. H. Hull and O. Brusdal, of this Laboratory, who made suggestions concerning the geometry of the diamond and also machined and mounted it.

Rapid Estimation of the Specific Surface of a Powder

The rapid estimation of the specific surface of a powder falling in the sub-sieve size-range is a matter of considerable industrial importance; but the techniques available for this purpose are limited in number.

One of these rapid techniques is that which may best be described as the 'single observation photo-extinction method'. Owing, however, to the omission of an important variable, this test gives results which are subject to very considerable error, and it is the object of this communication to direct attention to an empirical correction which, while retaining all the advantages of the simple test, leads to results which have adequate accuracy for many industrial purposes.

In the 'single observation' test a known weight of the powder under analysis, suspended in a known volume of a suitable fluid, in an optical cell, is maintained in turbulent motion by means of a stirrer. A beam of light is projected across the cell and by means of a photo-cell, or similar device, the intensities of the incident and emergent beams are measured.

The 'specific surface' of the material is then calculated by use of the equation

$$S_m = \frac{4}{Cl} \log_e \frac{I_0}{I} \qquad (1)$$

where S_m is the measured 'specific surface' in cm.^{2}/gm., C is the concentration of the suspension in gm./cm.^{3}, l is the length, in cm., of the light path through the suspension and I_0 and I are the intensities of, respectively, the incident and emergent beams.

This expression is, however, not strictly accurate since it is based upon the assumption that, for a small particle, the light energy absorbed and scattered outside the small solid angle subtended by the photo-sensitive surface at the centre of the particle is directly proportioned to the cross-sectional area of the particle, whereas in fact this is not so.

It has been suggested by one of us[1] that for an industrial powder having a wide range of particle size an empirical correction for this variation of the extinction coefficient with particle size can be made by the use of the expressions

$$\begin{array}{rclrcl} 200 < & S_m & < 20{,}000 & S_b & = & 3.3\, S_m^{0.77} \\ & S_m & = 20{,}000 & S_b & = & 8{,}000 \\ 20{,}000 < & S_m & < 70{,}000 & S_b & = & 66\, S_m^{0.5} \end{array} \qquad (2)$$

where S_m is calculated from equation (1) and S_b is a better approximation to the true value.

In the derivation of these expressions it has been assumed that the density of the powder under test is approximately 3.5 gm./cm.^{3} and, furthermore, in the original publication the suggestion was supported by a very small amount of experimental evidence.

Recent reconsideration of the problem shows, however, that improved accuracy over a wider range of

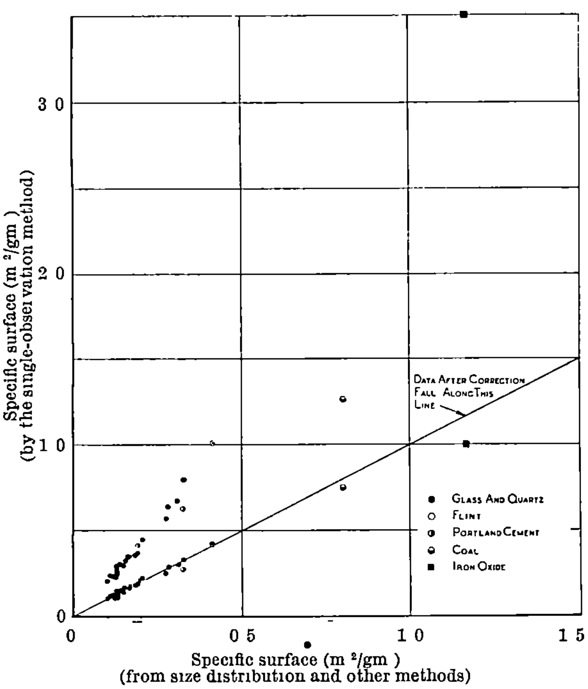

Fig 1

particle density can be obtained by the use of the modified equations

$$\begin{aligned} \frac{600}{\rho} < S_m < \frac{60,000}{\rho} \qquad & S_b = 4.5\rho^{-0.25}S_m^{0.77} \\ \frac{60,000}{\rho} < S_m < \frac{180,000}{\rho} \qquad & S_b = 120\rho^{-0.5}S_m^{0.5} \end{aligned} \tag{3}$$

During a recent research the specific surfaces of a number of samples of quartz and glass mill products have been determined from the size distribution curves (determined by photo-extinction methods) and by the single-observation test These results, together with those relating to a number of other materials, for which the specific surfaces have been determined by a variety of methods, are shown in Fig 1

In this figure are also shown these results after 'correction' by use of equations (3), and it is seen that these results, although suffering scatter, are in reasonable accord with the results deduced by other methods

Thus, it is considered that this method together with the above equations provides a rapid means for the estimation of the 'specific surface' or 'mean' particle-size of a powder, with an accuracy sufficient for many industrial purposes

Attention should, however, be directed to the following restrictions (1) The method is empirical and so should be applied with care (2) The correction equations are strictly applicable only to results obtained upon apparatus having approximately the same geometry as has the apparatus used for the original tests This geometry has been described elsewhere[1] (3) The correction equations are deduced for materials having a fairly wide range of size, for example fine mill products, and are not applicable to materials which have been artificially separated into very narrow size ranges (4) For values of S_m in the neighbourhood of $60,000/\rho$, there will, due to the complex behaviour of the extinction coefficient–particle size in this region, be considerable scatter, but even so the 'corrected' values, S_b, will be more nearly correct than will be the values of S_m

Effect of Temperature on the Rate of Setting of Gypsum Plaster

Experiments carried out in this laboratory with some commercial gypsum plasters show that, between 0° and 50° C , temperature may exert a comparatively small effect upon the rate of hydration of the calcium sulphate hemihydrate In most cases, the induction period (defined as the time for the rate of increase of temperature to exceed 0 1° C per min) of mixtures of plaster and water contained in a Dewar flask is constant from 0° to 40° C , and the maximum rate of increase of temperature reaches a feeble maximum at about 25° C [1], although there are minor but distinct deviations from this pattern (see, for example, Fig 3) Similar results have been found by Householder[2]

The effect of temperature on the rate of setting of a number of dental plasters has been subjected to a careful study by Worner[3], who found that the rate was roughly constant between 20° and 60° C but, unlike my results, dropped sharply below 20° C or a few degrees lower His plasters also showed minor variations in behaviour The parameters (induction period and maximum rate of increase of temperature) that I have used are measures of the rate of hydration of the hemihydrate, whereas Worner used the Gillmore test, which gives a measure of the stiffness of the mixture of plaster and water Recent work[4,5] strongly supports the view that the dominant process in the thickening of mixtures of plaster and water is the formation of an interlocking network of crystals of calcium sulphate dihydrate, although some previous authors have supported a colloidal mechanism[6,7] It is then of interest to know whether or not the Gillmore test yields results which run parallel with the kinetic parameters of the reaction, and whether the sharp increase in setting time observed by Worner as the temperature falls below 15° C was a characteristic of his materials only I have consequently carried out Gillmore tests[8] on plasters, for which the induction periods and maximum rates were also determined

Figs 1–3 show the times for completion of the Gillmore initial and final sets, induction periods and maximum rates plotted against temperature for three plasters with different characteristics In making the Gillmore tests the samples were covered with paraffin oil to prevent surface drying (cf Worner[3]) With plasters *A* and *B* the maximum rate rises to a feeble maximum at about 25° C and the induction periods are roughly constant between 0° and 40° C Three other plasters studied in detail show the same behaviour Plaster *C* is unusual in that the induction period decreases below 10° C and the maximum rate is constant from 5° C to 30° C The initial set is complete about 15 min after the end of the induction period, and when variations in the maximum rate are taken into account it is seen that the Gillmore initial set does move parallel with the kinetic parameters of the hydration of the hemihydrate This confirms the view that the dominant process in setting is the formation of crystals of calcium sulphate dihydrate, as work reported elsewhere suggests that the end of the induction period marks the formation of a certain surface area of crystals of dihydrate[9].

Plaster *A* shows an increase in the time for the completion of initial set below 30° C. but not the sharp effect shown by Worner's plasters. I have used retarder-free building plasters which had been stored in air-tight containers until they gave steady results and were generally very much slower in setting than Worner's plasters. Work reported in part elsewhere[9] suggests that the rate of hydration of calcium sulphate hemihydrate in plaster pastes is determined by the density of nuclei for the crystallization of the dihydrate, the effective surface area of the dihydrate present at the beginning of the reaction, and the rate of supply of calcium and sulphate ions to the surface of the growing phase. Reduction of temperature will tend to reduce the rates of dissolution of the hemihydrate and diffusion of calcium and sulphate ions, and I have already shown that in a number of plasters the density of effective nuclei increases as the temperature is lowered[1]. Another factor is the increase in solubility of the hemihydrate as the temperature is lowered. Whether the rate of hydration rises or falls as the temperature is lowered depends upon which of these effects predominates. The high rates for the plasters used by Worner suggest that they were heavily seeded with nuclei. If these were mostly greater in size than the critical nucleus it is possible that the density of effective nuclei did not increase relatively as greatly as in the cases I have studied, so that the time for completion of the initial set would increase more markedly as the temperature was lowered. It is noteworthy that the effect is relatively more marked in the most reactive plasters quoted by Worner. However, the magnitude of the effects observed by Worner at low temperature appears too large to be compatible with the assumptions upon which my theory is based[9].

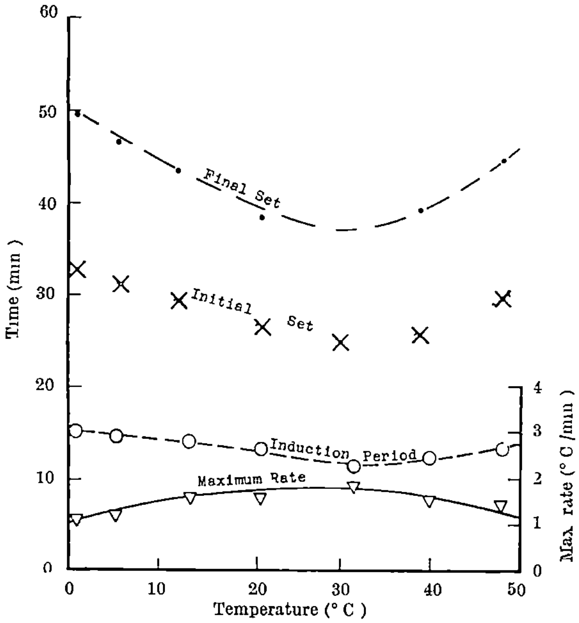

Fig. 1. Times for completion of initial and final set (average of four measurements), induction period and maximum rate of increase in temperature plotted against initial temperature for 100 gm. plaster *A* and 60 ml. water

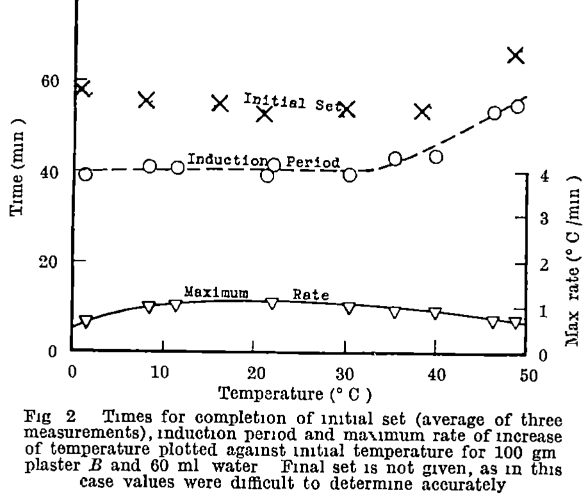

Fig. 2. Times for completion of initial set (average of three measurements), induction period and maximum rate of increase of temperature plotted against initial temperature for 100 gm. plaster *B* and 60 ml. water. Final set is not given, as in this case values were difficult to determine accurately

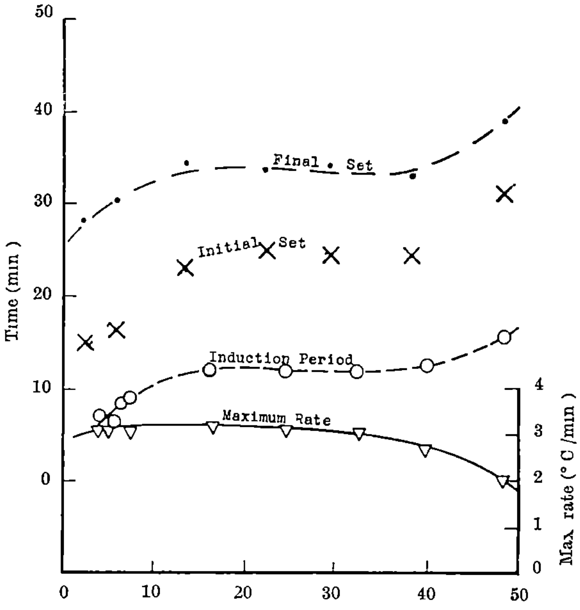

Fig. 3. Times for completion of initial and final set (average of two measurements), induction period and maximum rate plotted against initial temperature for 100 gm. plaster *C* and 60 ml. water

This investigation forms part of the programme of work carried out within the Division of Building Research and sponsored by the Associated Fibrous Plaster Manufacturers of Australia.

I wish to thank Mr. A. R. Docking, director of the Commonwealth Bureau of Dental Standards, for the loan of the Gillmore apparatus, and Mr. K. I. Lardner of this Division for assistance with the experimental work.

Forces between Titanium Dioxide Pigment Particles

Electron microscope techniques have been used for obtaining information on the nature of the aggregation process occurring between particles of titanium dioxide pigment in the dry state.

A cloud of air-dispersed rutile titanium dioxide pigment was formed by passing air from a high-pressure jet through a flask containing the dry pigment. The degree of dispersion in this cloud was assessed by collecting a specimen on a 'Formvar'-coated electron microscope specimen grid (Fig. 1). To examine the aggregation properties of the pigment, an electron microscope grid, without a specimen supporting film, was held in the pigment cloud for periods of 1 min. After each period, electron micrographs were taken of a selected area of the grid. Fig. 2 shows 'chains' of pigment particles adhering to the copper grid; with further exposures to the pigment cloud, a network of pigment particles was gradually built up (Figs. 3 and 4). Stereo-micrographs have indicated the three-dimensional nature of this structure.

An enlarged portion of a typical pigment network (Fig. 5) illustrates the high proportion of contacts in the direction of the *c* axis of the crystal, at the pyramidal faces.

From the maximum lengths of chains supported at only one contact, the force of adhesion between two particles was calculated as $\gg 6 \times 10^{-7}$ dynes.

Possible forces causing the aggregation are:

(*a*) *Van der Waals—London forces.* For two spherical particles of equal radius, the attractive force is defined by the relation

$$V = -A/6\ \{2/(S^2-4) + 2/S^2 + \log_{10}[(S^2-4)/S^2]\}$$

where V is the energy of interaction between the two spheres; A is a constant $\sim 10^{-12}$ ergs; $S = R/a$; R is the separation between the centres of the spheres; a is the radius of the two spheres[1]. For two pigment particles with equivalent spherical radii of $0{\cdot}2\mu$ and a separation of $0{\cdot}005\mu$ between surfaces (the approximate limit of resolution of the available electron microscope) the attractive force is $\sim 7 \times 10^{-6}$ dynes.

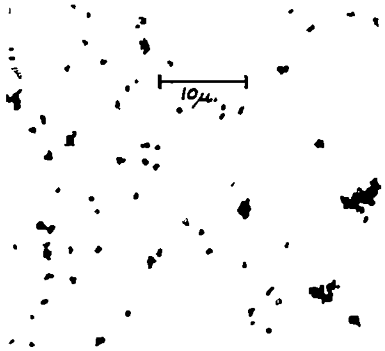

Fig. 1

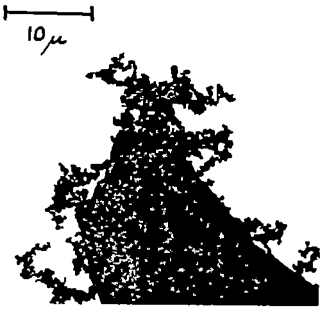

Fig. 2

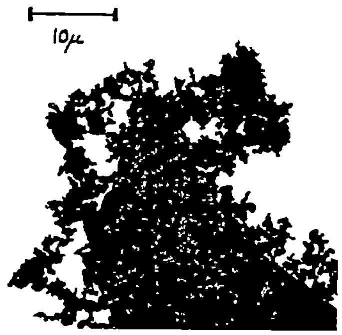

Fig. 3

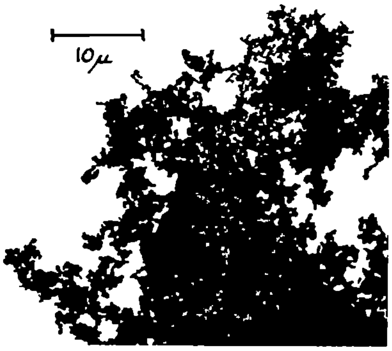

Fig. 4

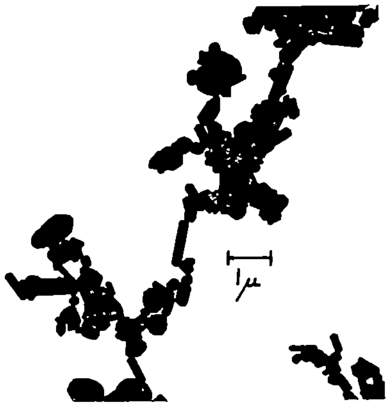

Fig. 5

(*b*) *Induced electrostatic forces.* A particle which has previously been charged by frictional processes in the original dispersion can induce an electrical polarization in an uncharged particle passing within its field. This polarized particle would then be attracted to the original particle and be available for the polarization of other particles in the pigment cloud. The force between two unit electronic charges at a separation of $0{\cdot}005\mu$ is of the order of 1×10^{-6} dynes, a value consistent with the attractive force calculated from the electron micrograph.

Work on the semi-conducting nature of titanium dioxide supports this hypothesis. It has been observed that high temperatures enhance the aggregation in dry pigments. High temperatures also lead to an increased electronic mobility in titanium dioxide[2] A similar phenomenon has been observed with dry quartz sand[3] The electronic conductivity of rutile titanium dioxide below 300° C is at a maximum along the c axis of the crystal[2], this is consistent with the orientation of the particles in Fig 5 On the evidence available at present, we prefer this mechanism to that described in section (a)

Temperature Variation of the Principal Magnetic Moments of Co^{++} Ions and the Asymmetry of the Crystalline Electric Field in Cobalt Acetate Tetrahydrate

The ground-state of the free divalent cobalt ion is $3d^7$, $^4F_{9/2}$, and the potential due to the crystalline electric field in the neighbourhood of the six co-ordinated cobalt ion conforms to

$$V = D(x^4 + y^4 + z^4) + Ax^2 + By^2 - (A + B)z^2$$

the fourth-order terms in the expression represent the cubic, and the quadratic terms the rhombic, part of the field The observed magnetic properties can then be explained on the assumption that the field is predominantly cubic in symmetry with a feeble rhombic component superposed If the field is due to an octahedral distribution of water molecules around the Co^{++} ion, the seven-fold orbital degeneracy is split into two triplets and a singlet, and the sign of the cubic field coefficient is such as to make one of the triplets the ground-state, the separation of which from the other triplet is of the order of 10^4 cm $^{-1}$ With such a disposition of the orbital Stark pattern, the components of the lower triplet being further separated to the extent comparable to kT by the rhombic part of the field, and the spin-degeneracy slightly raised through the spin-orbit coupling, the calculations of the principal magnetic moments naturally become very complicated Schlapp and Penney[1] have, however, made detailed theoretical calculations of the principal magnetic moments of cobalt salts Assuming the cubic field to be always of the same intensity, and one of the rhombic field constants zero, they assign different values to the other, namely, $A = 0$, 40, 200, etc With a small rhombic field the effective magnetic moments naturally become different, but they decrease in more or less the same way as with a purely cubic field when the temperature is lowered The principal moments separate out further when A is 200, and with the fall of temperature the moment having the largest value increases, reaches a maximum and then falls, while the other moments decrease From the experimental magnetic data on cobalt salts[2] it seems that the rhombic field in them is not so strong as to produce a rise in the maximum magnetic moment referred to above

In the Tutton salts the field is determined almost wholly by the octahedron of water molecules immediately surrounding the ion, and hence the deviation from the cubic symmetry will be small If, on the other hand, the members of co-ordination of the cobalt ion be not all alike, then there will be a possibility of the rhombic field becoming stronger It seems that cobalt acetate tetrahydrate is a case in point as revealed from its fine structure studies by X-rays[3] The space group is $P2_1/c$, and the unit cell contains two molecules Each cobalt ion is surrounded octahedrally by four water molecules and two oxygens of acetate groups The cobalt–water (2 11 and 2 06 A) and the cobalt–oxygen (2 12 A) distances suggest that as in nickel salts, the moment in the plane containing the Co^{++} ion and the oxygens of water molecules and of acetate groups is greater than in the direction normal to it

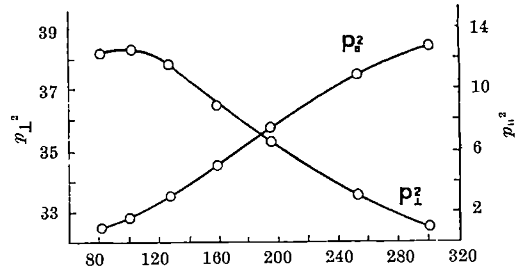

Fig 1 Variation of magnetic moments with temperature for cobalt acetate

The room temperature measurements[4] show that the magnetic anisotropy of cobalt acetate is highest of all the cobalt salts studied so far, and it clearly indicates a strong non-cubic field We have, therefore, measured the temperature variation of the principal magnetic susceptibilities of the crystal down to liquid air temperature The results are shown graphically in Fig 1 The trend of the magnetic moment versus temperature curves supports the existence of a strong rhombic field around the Co^{++} ion in $Co(CH_3COO)_2 4H_2O$

The work will be reported upon more fully elsewhere

Visible Absorption Spectra of Copper-ethylene-diamine-*bis*(acetylacetone) in the Crystalline State

For square planar copper complexes the crystal field theory predicts a splitting of the five-fold degenerate d-orbital energy-levels into four energetically different levels, d_{xy}, d_{z^2}, $d_{x^2-y^2}$ and $d_{zx}(d_{yz})$, in the order of diminishing energy[1] The visible absorption in these systems is associated with the transitions from d_{zx} (d_{zy}) to d_{xy} (w_1), from $d_{x^2-y^2}$ to d_{xy} (w_2), and from d_{z^2} to d_{xy} (w_3), where w_1 is the shortest wave-length and w_3 the longest wave-length band with w_2 in between The absorption spectra of square planar copper complexes in solution invariably consist of one broad absorption band in the visible region, which, however, could be resolved into three component bands by Gaussian analysis[2] With the object of finding if these split levels could be detected in the absorption spectra of the single crystal of a square planar copper complex, the present investigation was undertaken on the absorption spectra of an elongated platelet of copper-ethylene-diamine-*bis*(acetylacetone)

The optical part of the experimental equipment consisted of a single filament tungsten lamp, Hilger glass prism monochromator and a Leitz polarizing microscope The electrical part consisted of a 1*P*21 photomultiplier tube, a high-voltage stabilized power-supply unit and a stabilized d c -voltage amplifier The crystal was placed on the stage over a glass slide, and was brought to focus visually The eye was then replaced by the phototube assembly The objective – eye-piece combination used was such that the crystal completely covered the field in any orientation The orientation of the plane of polarization of the incident beam with respect to the long axis of the crystal could be varied either by rotating the polarizer or by rotating the stage with the crystal

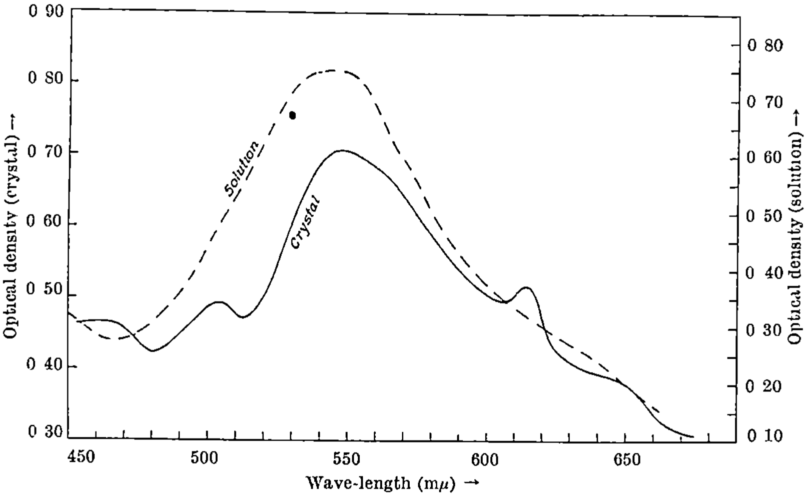

Fig 1

In Fig 1 the full-line curve represents the absorption spectrum of the crystal with the incident light polarized along the long axis of the crystal The curve shows three peaks at 505 mμ, 545 mμ and 615 mμ respectively The dotted curve represents the absorption spectrum of the same chelate in alcoholic solution It is evident that the spectrum in solution consists of one broad band with no fine structure By Gaussian analysis the solution band may be resolved into three bands with peaks at 510 mμ, 545 mμ and 600 mμ, which correspond fairly well with the three peaks observed in the spectrum of the crystal

With the incident light unpolarized or polarized at right angles to the long axis of the crystal, the absorption spectra were almost identical with those given in Fig 1, apart from a slight loss in the fine structure

Thanks are due to M/S Emission Radio and Varieties, Calcutta, for their kind help in constructing the electrical part of the measuring instrument

Possible Asymmetry in the Daily Range of the Geomagnetic Vertical Intensity around the Magnetic Equator

IN a recent paper, I have suggested that if the indication of an asymmetry in the daily range of the geomagnetic vertical intensity (Z) on opposite sides of the magnetic equator (higher ranges to the south) is confirmed, it might be explained by the opposition in phase of the equatorial electrojet effect on Z and the normal Z-variation on one side and the agreement of their phases on the other[1]

Magnetograms have now been obtained from Zaria, a new magnetic observatory in Nigeria on the northern side of the magnetic equator and about the same distance from that equator as Ibadan is south of it Zaria is thus near the latitude on the northern side at which the effect of the electrojet on Z-variation should be greatest, as Ibadan is supposed to be near the latitude of maximum to the south An examination of Z-variation at Zaria shows that the daily ranges of Z are as high as at Ibadan and the two Indian stations to the south of the magnetic equator occupied by Pramanik and Yegnanarayanan[2] Therefore, Zaria does not confirm the asymmetry It may still be necessary to record variations of the vertical force at a number of other stations on both sides of the equator before a definite statement can be made on the existence or otherwise of an asymmetry

Even if the asymmetry is confirmed, it is not likely to be explained by the phase relationship as simply as put in my paper[1] In the first place the consideration leading to the statement involved an error in reversing the direction of the Z-effect of the jet current during day-time Secondly, the true position is not so simple because the phase relation at places close to the geographical equator would change as the S_q-current system moves northwards or southwards according to season The situation is further complicated by possible movements of the electrojet itself according to season It is considered that further investigation should wait until it is known whether and how the electrojet moves according to season

September	191	194	178	183	153	103	83	71	50	36	16	1	0
October	196	194	174	181	147	100	81	70	49	33	17	1	0
November	197	197	169	—	143	97	80	68	48	31	16	0	0
December	197	197	167	—	140	95	82	64	46	28	15	0	0

of values between the two periods 1749–85 and 1918–54 is most striking

This fact has been used in our service for ionospheric predictions almost from the beginning of the present cycle, but with the increase in activity marked differences appeared It was realized, however, that a good fit could be obtained by multiplying figures observed 169 years before by a factor of proportion Using running means over 13 months and taking July 1784 as a starting date, linked to April 1954, the following equation was obtained in November 1956

$$\bar{x} = 1\;488\,\bar{y} - 12\;5 \qquad (1)$$

where $\bar{y}$ is the value for a particular month of the old cycle and $\bar{x}$ the corresponding value for the present cycle

In Table 1 predicted sunspot numbers (*p*), calculated in November 1956 with the above formula, are given for 1957 and 1958 and compared with the available Zurich observational values (*o*)

The mean square root of deviation between observed and predicted values is 1 6 sunspot, which is very small indeed

Using the data of April 1954–October 1958, a new equation has been derived for a still better fit

$$\bar{x} = 1\;527\,\bar{y} - 13\;4 \qquad (2)$$

Although the change between equation (1) and (2) is very small, this last has been used for the prediction of sunspots as listed in Table 1 from 1959 until the end of the cycle in January 1968 From November 1966 the formula gives negative values, these have been replaced by zeros

Owing to the very empirical way in which these figures have been derived it is essential to keep a close check with observations as they appear

However good the relationship between the old and the new cycle has been for the past five years, it does not mean, unfortunately, that it will remain so with certainty in the future

Without theoretical support, nothing better can be expected for such long-term prediction

Anomalous Continuum Radiation from Jupiter

FOLLOWING the report of Dr Frank D Drake[1], of the National Radio Astronomy Observatory, that Jupiter emits anomalously large amounts of continuum radiation in the vicinity of 21-cm wavelength, observations of Jupiter were undertaken with the Harvard 60-ft radio telescope With the instrument used as a direct radiometer with a bandwidth of 2 Mc /sec in the vicinity of 1,420 Mc /sec, a signal of amplitude several times the noise fluctuation was found in the expected position of Jupiter on most traces. The averages of at least five right-ascension drift curves were used to obtain the antenna temperatures given in Table 1 The probable error is less than 0 15° K

Table 1

Time (U T)	Date	No of curves averaged	T_a (° K)
0203–0403	May 16, 1959	5	0 51
0408–0608	,, 16 ,,	5	0 73

0048–0430	,, 2 ,,	6	0 64
0434–0718	, 2 ,,	7	0 37

The results show that the amount of the emission varies with time, by as much as a factor of 2 in a period of a few hours Attempts are now being made to compare these variations with solar effects and with the low-frequency bursts that are known to come from Jupiter[2], as well as with periodicities due to Jupiter's rotation

An antenna temperature of 1° K would correspond in our case to a brightness temperature of 6,200° K over the surface of Jupiter This high value, together with the time variations, seems to rule out a thermal origin for this radiation The calibration of our system has depended on nightly observations of Virgo *A*, the intensity of which at 1,420 Mc /sec is assumed to be the same as that measured recently by Westerhout[3] at 1,390 Mc /sec

CHEMISTRY

The Coloured Product of the Sakaguchi Reaction

We have already reported[1] that the coloured product of the Sakaguchi reaction[2] (between arginine and α-naphthol) behaves as a typical acid-base indicator, being red in alkali and yellow[3] in acid It has now been found that the compound behaves as an oxidation-reduction indicator also

Long strips of Whatman No 1 filter paper (3 in × 22 in) were soaked in a 0 4 per cent solution of arginine hydrochloride, and dried Colour was then developed, as described earlier[1,3], by dipping first in a solution of 100 mgm α-naphthol, 1 gm urea and 2 5 gm potassium hydroxide in 100 ml ethanol, and finally in a solution of 0 75 gm bromine in 100 ml 5 per cent aqueous potassium hydroxide The colour was dissolved in a minimum quantity of water and the solution, after being acidified with hydrochloric acid (*p*H 2–3), was left overnight in a refrigerator By washing the resulting dark precipitate with cold acidified water and then extracting repeatedly with ether, considerable purification of the compound was achieved

It was observed that on adding a few drops of a freshly prepared solution of sodium dithionite to a dilute and slightly alkaline solution of the above substance, the red colour of the solution was instantly discharged On shaking the solution gently in air, however, the colour reappeared This reversible process could be repeated a large number of times with the same solution When acidified, the yellow colour of the solution could be similarly discharged by dithionite and restored by shaking in air These results were a clear indication of the redox nature of the compound It was found that the compound could also be reduced to the leuco form by stannous chloride, but not by ascorbic acid or cysteine

It appears from these observations that the coloured product of the Sakaguchi reaction has probably a quinonimine portion as its chief chromophore If so then, in view of our recent finding[4] that this reaction is in fact a general reaction of phenolic compounds but is specific for *para*-unsubstituted phenols (a few *p*-halophenols, which gave the reaction, were the sole exception to this rule), the compound must have a *p*-quinonoid structure (as distinct from an *o*-quinonoid one) It would thus appear that the mechanism of colour formation in the Sakaguchi reaction is presumably an oxidative coupling between a guanido compound and a phenol, somewhat as in the formation of an indophenol

Although the present finding, together with the *para*-unsubstituted-phenol specificity of the reaction[4], practically confirms our earlier suggestion regarding a *para*-linkage in the compound[1], it is clear, since the compound behaves as a redox system both in acid and alkali and so must have a quinonoid structure in either, that the variation of its colour in acid and alkali is not due to isomerization between a benzenoid and a quinonoid form as suggested earlier[1] but is due to other factors

The final purification of the compound is in progress with a view to its complete characterization These results, including the exact redox potential of the fully purified compound, will be published later elsewhere

I wish to thank Dr D K Roy and Mr J Datta for their helpful suggestions, and our director, Dr J C Ray, for his kind interest I am also glad to acknowledge the technical assistance of Mr T K Majumdar

Reaction-directing Properties of Non-enzymic Macromolecules: Pyrogallol Oxidation in the System Iron(III)–Cellulose

Although the plant cell wall is regarded as an inert substance, mechanical in function, recent studies have demonstrated wall polysaccharides to be active sites (matrices) in the directed polymerization of 4-hydroxyphenylpropene derivatives (such as eugenol) to lignins[1] Other investigations have shown the peroxidation of pyrogallol catalysed by iron(III) to be enhanced by low concentrations of non-enzymic deoxyribonucleic acid[2], and have emphasized both the qualitative and quantitative effects accruing from addition of solid surfaces to various chemical or biochemical systems[3-6]

To extend these views on the catalytic activity of biopolymer surfaces, the system iron(III)–cellulose has been included among those studied as an oxidase model and for its possible direct significance in biocatalysis as well

Among the experimental procedures employed, variables other than cellulose have included concentrations of pyrogallol/hydrogen peroxide (constant molar ratio maintained at 1 5) and iron(III) The formation of coloured oxidation products from pyrogallol at 0 1 and 1 0 m mole/20 ml (after incubation in darkness, at 24±1° C in 0 025 *M* potassium dihydrogen phosphate for 100 hr) was accelerated

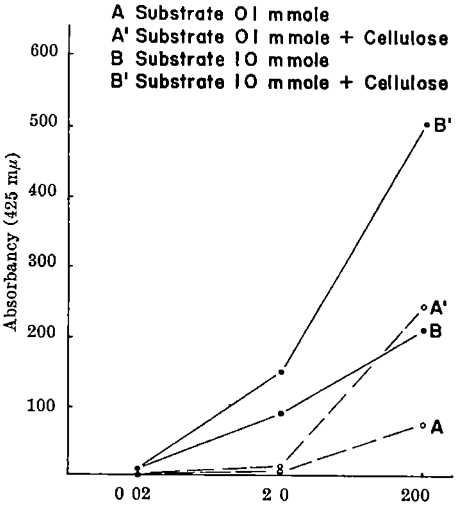

Fig 1

by cellulose (50 mgm Whatman No 42 filter paper) in the presence of iron(III) (Fig 1) With little or no metal ion, addition of filter paper had no effect, whereas at the highest iron(III) concentration 2×10^{-5} mole/20 ml (10^{-3} *M*), addition of filter paper enhanced the reaction 2–3-fold Essentially the same picture is presented both at low and high substrate-levels, however, the combination of intermediate iron(III) concentration (10^{-5} *M*) and low pyrogallol concentration permits only a slight effect of added cellulose, although the effect of cellulose is substantial at this metal ion concentration when more substrate is supplied

When visible (425 mμ, Bausch and Lomb 'Spectronic 20' spectrophotometer) and ultra-violet (260 mμ, Beckman *DU* spectrophotometer) absorbancies were compared, it was noted that, with increase in iron (III) from lowest to highest concentrations, visible absorption increased approximately 20-fold without cellulose and 50-fold in its presence in reaction mixtures with 1 0 m mole of substrate In the same circumstances, ultra-violet absorption increased approximately 5-fold without cellulose, but 15-fold in its presence In effect, then, the relative enhancement by filter paper was somewhat greater when measured in the ultra-violet region The relative effects noted at the lower concentrations of pyrogallol stand in sharp contrast to the preceding, for although there is a 3-fold effect of added filter paper at the highest iron(III) level, only a slight effect (5–20 per cent) of cellulose was in evidence when measurements were made at 260 mμ

The absence of the cellulose effect as measured in the ultra-violet at lower concentrations of pyrogallol and its presence at higher substrate-levels was confirmed separately in a similar experiment using 10^{-5} *M* iron(III) but only a 12-hr reaction-time (Table 1) Here the level of pyrogallol was increased still further, and the products deposited in the filter paper taken into account The importance of substrate concentration is evident here, as the greatest enhancement by added cellulose is found at 1 0 m mole pyrogallol, with a far smaller effect at 10 0 m moles, and essentially none at 0 1 m mole

Table 1 EFFECT OF SUBSTRATE LEVEL AND CELLULOSE ON PYROGALLOL OXIDATION

Pyrogallol (m moles/ 20 ml)	(*a*) Control supernatant	(*b*) Cellulose supernatant	(*c*) In cellulose (extract)	Ratio (*b* + *c*)/*a*
0 1	1 00*	1 00	0 05	1 05
1 0	7 98	14 17	4 52	2 34
10 0	132 0	158 7	5 02	1 24

* Arbitrary, all other absorbancies (260 mμ) computed relative to this value

Substances formed during the oxidation of pyrogallol under the various experimental conditions employed here have not as yet been isolated and characterized chemically, however, some indications as to the diversity of these products have been obtained

The evidence presented here shows the iron(III)-catalysed homogeneous oxidation of a phenol to be enhanced by the presence of a water-insoluble macromolecule of comparatively low reactivity The formation of a two-component catalyst is reminiscent of reconstitution of peroxidases from their separated protein and hæm moieties

The role of a cellulose matrix in biosynthetic processes other than lignification remains a matter of conjecture, but present evidence suggests the importance of the cell wall in biochemical processes

Analysis for Magnesium in High-Purity Aluminium

ALTHOUGH there are several methods for determining magnesium in aluminium, very few of these can be used successfully in the low concentration range High-purity aluminium, as supplied by most aluminium manufacturers, usually contains magnesium in the range 1–50 p p m Pohl[1] has developed a chemical method for concentrating the impurities and afterwards analysing by spectroscopy We have developed a distillation method to concentrate the impurities which is more specific than that of Pohl, after the concentration the analysis can be completed by any convenient method

The aluminium stocks analysed were obtained from various suppliers and were supplied as 99 99 or 99 999 per cent pure The apparatus used for the distillation consists of a 'Vycor' bell jar connected to a conventional high vacuum system The sample was heated by induction, and the temperature was determined with an optical pyrometer A graphite plate supported the sample The graphite was of a pure grade which has been developed for nuclear applications, and it had been heated to a high temperature to get rid of any possible magnesium contamination

The procedure is as follows a 10-gm sample (either one piece cut from the billet or a composite) is wet ground, degreased in fresh methanol, etched in concentrated potassium hydroxide and weighed It is then held at a temperature just below the melting point in the apparatus until degassing is completed (10^{-5} mercury) Afterwards, the temperature is raised to 925–1,000° C and held for 10–15 min in a vacuum of about 10^{-5} mm mercury After cooling, the distilled metal which had been condensed on the bell jar is dissolved in distilled hydrochloric acid or aqua regia prepared from distilled acids The solution is analysed by spectroscopy or other convenient means Limited experience indicates that the same results may be obtained by using a small sample, 1 gm, in a graphite or alundum crucible heated in vacuum by a resistance furnace

Results for four aluminium stocks are given in Table 1

There is a small temperature effect in the analysis There is also a small effect of the magnesium/aluminium ratio in the solution, which variation is affected by variation in the time and temperature of distillation However, both these effects are quite small, and the greater errors are those of routine spectro-

Table 1

Aluminium stock	No of samples	Time (min)	Temperature (° C)	p p m magnesium (± average deviation)
A	4	14	950	1 6 ± 0 2
B	4	13	940	1 1 ± 0 2
C	2	12	950	8 6 ± 0 6
D	7	12	920	11 4 ± 3 2
D	3	15	1,000	12 6 ± 1 0

graphic analyses The minimum concentration of magnesium in aluminium which can be found by this method is about 1 p p m

In addition, the concentrations of other low-melting impurities, such as zinc, lead, bismuth and cadmium, may be determined spectroscopically from the acid solutions

We wish to thank J P Faris, B H Meng and M R Trahey for the spectroscopic analyses This work was done under the auspices of the U S Atomic Energy Commission

Volatile Methoxides of Aluminium and Zirconium

THE methoxides of the alkali metals, magnesium, aluminium and zirconium were considered to be non-volatile due to their being either ionic or highly polymeric covalent in nature Thus by contrast the penta-methoxides of quinquevalent niobium[1] (dimer), tantalum[2] (dimer) or uranium[3] (trimer) may be distilled under a pressure of 0 1 mm. mercury According to our structural theory for metal alkoxides[4] it seemed possible that the degree of polymerization of aluminium trimethoxide or zirconium tetramethoxide could be as low as 8-fold and approximate calculations suggested that such compounds might be volatile at temperatures greater than 200° C Moreover, recent studies on the thermal stability of metal alkoxides[5] suggested that the methoxides would remain stable up to about 400° C Accordingly we have attempted to sublime some of the 'non-volatile' methoxides in an all-glass molecular still at very low pressure

Aluminium methoxide A sample prepared by the reaction catalysed by mercuric chloride and involving aluminium foil and methanol was heated at 150° C and about 10^{-5} mm mercury and after 24 hr a trace of sublimate had appeared The temperature was then raised to 240° C and a rapid sublimation occurred (found. Al, 22 7 , OMe, 77 2 per cent, $Al(OMe)_3$ requires Al, 22 5 , OMe, 77 5 per cent) It was noticed that freshly sublimed aluminium methoxide dislodged from the cold finger volatilized much more rapidly than the original unsublimed material and suggested a difference in their degrees of polymerization (see ref 4 on 'ageing' of aluminium alkoxides) Samples of sublimed and unsublimed compound were sealed-off in capillaries for X-ray powder photographs The sublimate gave a broad diffraction ring of small radius (Fig 1*A*) suggesting a low order of crystallinity while the unsublimed material gave a similar picture (Fig 1*B*) but with an additional ring of larger diameter Both samples were then exposed to the atmosphere by breaking the ends of the capillaries In each case X-ray pictures showed that hydrolysis had caused a complete breakdown of structure Another sample of sublimate kept in a sealed capillary for one month showed no change in diffraction pattern Similarly, a sample of sublimate kept in contact with dry methanol for a month also showed no major structural change On the other hand, microscopic examination of sublimate suspended in benzene showed that it was initially isotropic but during one month became anisotropic (straight extinction) with isotropic bands It appears, therefore, that the methoxide exhibits a structural 'ageing' effect although the low degree of order in the solid makes difficult the observation of this effect by X-ray powder photography It was also noteworthy that the freshly sublimed compound was practically insoluble in methanol or benzene

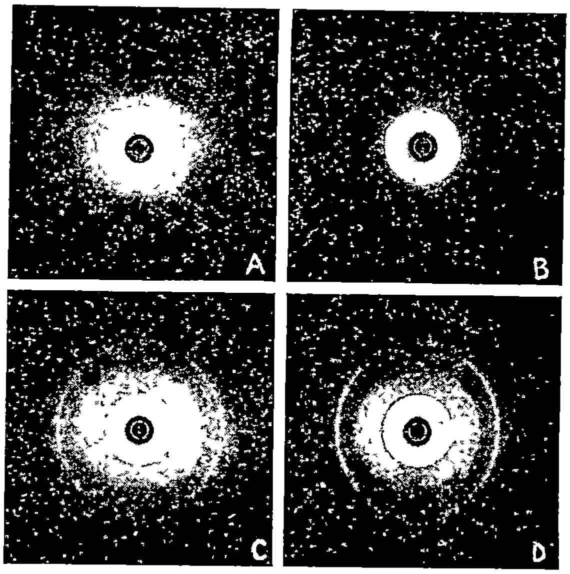

Fig 1

Zirconium methoxide A sample was prepared from redistilled zirconium tetra-*tert* -amyloxide by repeated treatments of the precipitated solid with fresh quantities of boiling methanol Finally the zirconium tetramethoxide (found Zr, 42 2 per cent , $Zr(OMe)_4$ requires Zr, 42 4 per cent) was dried at 190° C and 0 1 mm mercury A sample heated in the molecular still at 250° C slowly gave a sublimate but at 280° C sublimation was rapid and complete (found Zr, 42 6 , OMe, 57 1 per cent , $Zr(OMe)_4$ requires Zr, 42 4 , OMe, 57 6 per cent) X-ray powder diffraction patterns of the sublimed (Fig 1*C*) and unsublimed (Fig 1*D*) solids were very similar and showed a large number of well-defined rings indicating a highly crystalline substance Exposure of the samples to the air caused destruction of the patterns except for one diffuse ring of large diameter The solids were anisotropic

Lithium, magnesium and lanthanum methoxides None of these solids showed any evidence of sublimation at 360° C during a period of 18 hr in the molecular still but they remained completely stable This does not prove that these compounds are ionic and indeed the structural theory would suggest that if they are covalent the lithium and magnesium methoxides should be giant polymers (assuming co-ordination numbers of 4 and 6 for lithium and magnesium respectively) while the minimum polymer for $La(OMe)_3$ with 6 co-ordinated lanthanum would be an octamer (note that lanthanum *tert*-butoxide is volatile[6])

We thank Dr H Carlisle for assistance with the X-ray studies and the Director, Atomic Energy Research Establishment, Harwell, for permission to publish these results

BIOCHEMISTRY and PHYSIOLOGY

Role of the Coenzyme in the Stabilization of Glyceraldehyde-3-phosphate Dehydrogenase

THE role of a coenzyme is studied mostly with respect to the mechanism of reactions catalysed by specific enzymes It has been established in some cases that coenzymes and prosthetic groups have a protecting and stabilizing effect on the protein molecule It is known that the large molecule of D-glyceraldehyde-3-phosphate dehydrogenase (PGAD) (molecular weight 140,000) is labile, and does not contain disulphide linkages as stabilizing bonds[1]

According to Velick crystalline D-glyceraldehyde-3-phosphate dehydrogenase from rabbit skeletal muscle binds firmly 3 moles of diphosphopyridine nucleotide (DPN) per mole of protein[2] We have found that crystalline D-glyceraldehyde-3-phosphate dehydrogenase from beef, pig and dog also bind firmly the same amount of coenzyme[3] It is presumed[1] that the firmly bound diphosphopyridine nucleotide has a stabilizing role and, as we have previously found, in the presence of excess diphosphopyridine nucleotide D-glyceraldehyde-3-phosphate dehydrogenase is fully resistant to the proteolytic action of trypsin[4] Therefore, we studied the role of diphosphopyridine nucleotide in connexion with its stabilizing effect on the D-glyceraldehyde-3-phosphate dehydrogenase molecule, by measuring the changes in the specific optical rotation, intrinsic viscosity and digestibility occurring as a result of displacement of the bound coenzyme from the enzyme molecule by charcoal treatment and *p*-chloromercuribenzoate (PCMB) blocking[1]

The experiments were carried out with four times recrystallized pig D-glyceraldehyde-3-phosphate dehydrogenase, prepared according to the method of Elödi and Szorényi[3], in a 0 1 M phosphate buffer at *p*H 8 4 Displacement of the bound diphosphopyridine nucleotide was assessed spectrophotometrically at the wave-lengths 250–290 and 330–370 mμ The results are given in Table 1

Table 1 THE EFFECT OF DISPLACEMENT OF THE BOUND COENZYME ON SOME PROPERTIES OF D-GLYCERALDEHYDE-3-PHOSPHATE DEHYDROGENASE

PGAD tested	Spec opt rotation $[\alpha]^{20}_{D}$	Intrinsic viscosity $[\eta]$	Digestibility* by trypsin in 30 min at 35° C
1 Control PGAD $(DPN)_3$	−30 6°	1 95	1 00
2 Control + 3 equiv PCMB	−40 8°	7 80	2 80
3 Charcoal treated	−41 6°	7 30	3 10
4 Charcoal treated + 3 equiv DPN	−29 8°	1 90	0 70
5 Charcoal treated + 6 equiv DPN	−31 4°	2 40	0 14
6 Charcoal treated + 15 equiv DPN	−31 4°	3 05	0 0†
7 Urea denatured	−99 7°	42 5	14 2

* Digestion was carried out with crystalline trypsin The extinction of the deproteinized reaction mixture and the amount of protein precipitable with 6 6 per cent trichloracetic acid were measured The digestibility of the control experiments has been taken arbitrarily as unity

† Digestibility after 3 hr incubation

It can be seen that the displacement of the bound coenzyme causes a change in the structure of the enzyme shown by the changed specific optical rotation and intrinsic viscosity and the enhanced digestibility These changes are in the same direction as those caused by denaturation, the effect, however, being much less pronounced than that caused by treatment with urea

Re-addition of the amount of diphosphopyridine nucleotide displaced from the protein molecule completely restores the initial properties Addition of a greater excess of coenzyme does not alter the optical rotation of the protein, but it increases its intrinsic viscosity and stabilizes the structure of the enzyme against proteolysis

The above results suggest that the bound diphosphopyridine nucleotide stabilizes the structure of the enzyme molecule in a given configuration, which may be necessary to the catalytic action The effect found with excess diphosphopyridine nucleotide requires a more extended experimental analysis

The details of these experiments will be published in *Acta Physiologica Academiae Scientiarum Hungaricae*

ε-N-Methyl-lysine in Bacterial Flagellar Protein

FLAGELLAR proteins (flagellins) from several species of bacteria have been studied by Weibull[1] and, more recently, by Koffler[2] The present investigations have revealed differences in the amino-acid compositions of the flagellins from *Proteus vulgaris*[2] and *Salmonella typhimurium* (Table 1) Also the latter protein has been found to contain ε-N-methyl-lysine, an amino-acid that has not been previously found to occur naturally

Table 1 AMINO-ACID COMPOSITION OF FLAGELLINS
From (*A*) *Salmonella typhimurium SW*1061 two independent determinations
From (*B*) *Proteus vulgaris* (Koffler, ref 2) recalculated for comparison purposes
Results expressed as gm residues/10^5 gm protein

	(*A*)		(*B*)
Glycine	79	81	86
Alanine	147	150	110
Valine	60	60	64

*iso*Leucine	49	46	56
Glutamic acid	96	96	97
Aspartic acid	155	153	166
Serine	59	57	68
Threonine	101	99	85
Tyrosine	20	27	13
Phenylalanine	13	14	24
Tryptophan	0	0	0
Proline	13	9	0
Cystine/2	0	0	6
Methionine	3	3	7
Lysine	33	31	49
ε-N-methyl-lysine	28	24	0
Arginine	24	29	40
Histidine	4	0	0
Total residues	958	955	957
Amide groups	156	152	144

ε-N-methyl-lysine was identified in hydrochloric acid hydrolysates of the flagellin by paper electrophoresis, and by chromatography on paper (Fig 1) and ion-exchange resin In several systems the amino-acid from flagellin behaved in a similar way to a sample of synthetic ε-N-methyl-lysine (obtained from Dr F Sanger Neuberger and Sanger[3]), and could be differentiated from the isomeric α-N-methyl-lysine and homolysine The ε-N-methyl-lysine from flagellin was separated from the other hydrolysis products by ion-exchange chromatography, and was crystallized as the monohydrochloride Elementary analysis agreed with the formula $C_7H_{17}N_2O_2Cl$ (calculated C, 42 8, H, 8 65, N, 14 3, found C, 42 7, H, 8 91, N, 14 5) The bacteria were found to incorporate lysine-^{14}C into the flagella both as lysine and as the new amino-acid, under conditions in which no other amino-acid was made radioactive Dinitrophenyl-flagellin, on hydrochloric acid hydrolysis, yielded two yellow water-soluble components, namely, ε-dinitrophenyl-lysine and ε-dinitrophenyl-ε-N-methyl-lysine The latter was characterized by the R_F value, the absorption spectrum (with a maximum at 388 mμ), and by hydrolysis with an ammonia solution to give the free amino-acid Peptides from tryptic and chymotryptic digests of flagellin were separated by paper electrophoresis, several peptides were found to contain ε-N-methyl-lysine, and the ratio of lysine to ε-N-methyl-lysine varied from peptide to peptide, indicating that ε-N-methyl-lysine occurs at several sites in the polypeptide chain

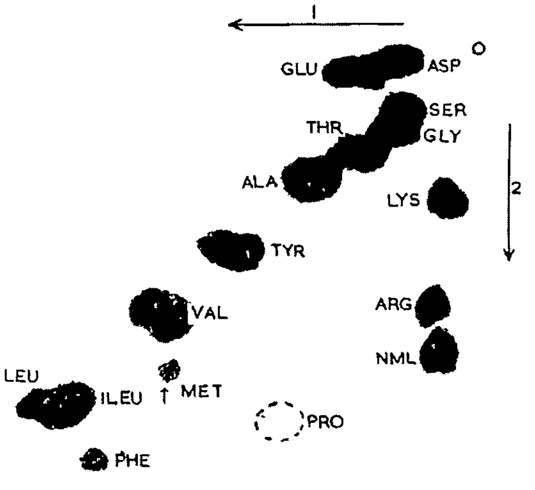

Fig 1 Two-dimensional chromatogram of a 24-hr 105° C, 6 *N* hydrochloric acid hydrolysate of 0 2 mgm of *Salmonella typhimurium SW*1061 flagellin Method of Levy and Chung (ref 4) Solvent 1 *n*-butanol/acetic acid/water (4 1 5) Solvent 2 1 1 *m*-cresol/phenol, *p*H 9 3 borate buffer Whatman No 52 paper NML, ε-N-methyl-lysine

The organism used for most of the experiments was *Salmonella typhimurium* strain *SW*1061, and was normally grown on a broth/agar medium In the isolation of crystalline ε-N-methyl-lysine monohydrochloride, when large amounts of starting material were required, some flagella from other *Salmonella* species were used

Inhibitory Effect of Fungistatic Antibiotics on the Production of Amylase by *Penicillium chrysogenum*

THE washed mycelium of *Penicillium chrysogenum* is able to synthesize amylase in the presence of starch The production of this enzyme starts after 4 hr incubation independently of the original carbohydrate content of the medium 150–250 u enzyme/100 ml will be produced during further incubation for the next 4–6 hr This enzyme production was inhibited by 2,4-dinitrophenol (3 × 10^{-4} *M*) and sodium azide (10^{-4} *M*), but was not influenced by streptomycin (2,000 μgm/ml), chloramphenicol (200 μgm/ml) or oxytetracycline (500 μgm/ml) The effect of the fungistatic antibiotics on the production of the enzyme was examined under experimental conditions identical with those previously reported[1] Aqueous dilutions of solution of the fungistatic substances in methanol were added to the incubated mixture Amylase was determined by the method of Smith and Roe[2], the results (Table 1) show that production of this enzyme is very sensitive to the presence of the substances mentioned above

Shepherd[7] and Kerridge[8] observed that with *Aspergillus nidulans* and *Saccharomyces carlsbergensis*, respectively, synthesis of protein and of nucleic acid was inhibited by antibiotics only in growth-inhibiting concentrations Furthermore, Kerridge found[8] that 'Actidion' is able to influence the synthesis of the adaptive maltozymase system in concentrations

Table 1. INHIBITION OF AMYLASE PRODUCTION (PER CENT)

	Concentration of the antibiotics (μgm./ml.) 100	10	1	0.1	0.01
Nystatin (ref. 3)	100	100	90	45	25
Flavofungin (ref. 4)	95	20	0	0	0
Trichotecin (ref. 5)	100	80	60	10	0
T-substance* (ref. 6)	100	80	60	10	0

* A new antibiotic similar to trichotecin.

below that necessary to inhibit growth. Our results are similar to those cited. It is striking, however, that nystatin inhibits the production of amylase at a much lower concentration than other fungistatic antibiotics, at a concentration, moreover, at which it exerts no fungistatic action. This fact may play a prominent part in the therapeutical applicability of nystatin.

Detection and Identification of the Polyphenoloxidase Substrate of the Banana

BLACKENING of the fruit of the banana may occur during cultivation, when the cause is usually of pathological origin, or during storage if ripening is not adequately controlled. The biochemical changes involved in the blackening of the fruit have received little study, although evidence for the existence of an enzyme system in the fruit of the banana capable of oxidizing substances of the catechol type was presented by Onslow[1] in 1920. The existence of flavonoid compounds in the edible banana has been reported[2,3]. Robinson[2] detected delphinidin in the hydrolysis products of the pulp of an edible banana while Simmonds[3], who has described the anthocyanin pigments of the bracts of a number of banana species in detail, reported that the skin and pulp of fruit of the edible varieties contained large amounts of leucoanthocyanins. Indirect evidence was, however, obtained[3] that the polyphenol oxidase system of the banana was unable to act on the leucoanthocyanins present to produce brown colorations. Recently, the presence of serotonin and related compounds in the fruit of the banana was reported by Waalkes *et al.*[5] The ability of these compounds to serve as substrates for polyphenoloxidase was not, however, explored.

During the past year, chromatographic studies at the Imperial College of Tropical Agriculture have indicated that the major browning substrate of the edible banana is 3,4-dihydroxyphenylethylamine and have confirmed the opinion of Simmonds that the leucoanthocyanins present are not acted upon by banana polyphenoloxidase.

Two varieties of banana were utilized in these studies: the clone Gros Michel, which is extensively cultivated in tropical America and to a more limited extent in Jamaica for export, and the clone Mysore, which is grown wholly for local consumption. The polyphenols of the banana skin were extracted by macerating 25 gm. of tissue in 50 ml. of 1 per cent methanolic hydrochloric acid. After filtration, 0.02 ml. of this extract was applied to the chromatogram, which was developed with butanol/acetic acid/water (40:10:50). After drying, the chromatogram was sprayed with a polyphenoloxidase preparation and incubated in a humid chamber[6] until the browning changes were complete. A single zone showing intense darkening developed on the chromatogram and after drying its position was marked. By this means it was shown that the major browning substrate of the banana possessed an R_F of 0.42 in butanol/acetic acid/water. Although a large amount of stationary leucoanthocyanin was present on the base-line (evidenced by a high yield of the anthocyanidin, delphinidin on acid hydrolysis of the strip), no browning occurred in this region. These results were later confirmed by two-dimensional chromatography, in which primary development with 2 per cent acetic acid was followed by a secondary development with the butanol/acetic acid/water solvent system.

The enzyme preparations used to locate the browning substrate were (*a*) banana polyphenoloxidase, (*b*) cacao polyphenoloxidase[6] and (*c*) tyrosinase (from mushrooms, L. Light and Co., Ltd.). The last two enzymes were applied to the chromatogram as aqueous or buffered solution by means of a glass spray[6]. The application of the banana enzyme to the chromatogram was complicated by its relative insolubility in water, the activity being almost wholly lost on filtration. Since spraying the unfiltered suspension was impracticable, application of the enzyme preparation was effected by the following means: 25 gm. of banana pulp in 50 ml. of distilled water was homogenized in a microblender for 10 min., after which the crude suspension was applied to the chromatogram by means of a small nylon brush, which was dipped into the suspension and then caused to emit a spray by passing a glass rod firmly and rapidly over the bristles. The semi-solid suspension was thus evenly distributed over the chromatogram and on incubation a well-defined area of browning, corresponding in position to that given by the other polyphenoloxidase preparations, formed on the chromatogram.

Since the crude banana extract possessed similar activity to the well-characterized polyphenoloxidases of the mushroom and cacao, it is evident that a highly active phenol oxidizing system is present in the fruit of the banana, and it was shown that aqueous extracts of banana pulp possessed the ability to oxidize added (—)-epi-catechin and catechol at a rapid rate.

Comparison of the chromatographic properties of the browning substrate with those of the naturally occurring phenolic acids and flavonoids indicated that the substance did not correspond to any previously reported compound in either of these groups. With certain spray reagents, however, the colours given closely resembled those given by 3,4-dihydroxyphenylalanine, and it appeared that although the R_F values of these two compounds differed considerably, there was a strong possibility that the

Table 1

		Browning substrate	3,4-Dihydroxyphenylethylamine
R_F values	Butanol/acetic acid/water (40 10 50)	0 42	0 42
	2 per cent acetic acid	0 69	0 69
	phenol/sulphur dioxide (ref 5)	0 43	0 43
Spray reagents	*p*-nitro-aniline (ref 4)	brown→purple→black	brown→purple→black
	Potassium ferricyanide (ref 5)	pink→lavender	pink→lavender
	ultra-violet fluorescence after spraying with potassium ferricyanide	blue	blue
	1 per cent ethanolic ferric chloride	pale olive green	pale olive green

browning substrate was closely related chemically to the latter substance It was later shown that the browning substrate was chromatographically identical with an authentic specimen of 3,4-dihydroxyphenylethylamine (Delta Chemical Works Inc) (Table 1)

3,4-Dihydroxyphenylethylamine was shown to be present in both skin and pulp of the edible banana Although the amount present in the pulp was very much lower than that found in the skin, its presence was readily demonstrated chromatographically by a preliminary concentration of the pulp extract in a vacuum oven 3,4-Dihydroxyphenylethylamine was detected also in other parts of the banana plant, including the bracts of the flower Although the amine was present in large amounts, the corresponding amino-acid, 3,4-dihydroxyphenylalanine, was not detected in any of the extracts examined

Examination of banana skin in which blackening was pronounced showed that the content of 3,4-dihydroxyphenylethylamine was low or nil A similar decrease resulted when skin tissue was macerated in water Under these conditions an immediate darkening occurred and afterwards 3,4-dihydroxyphenylethylamine could not be detected in the reaction mixture When the maceration was carried out in 1 per cent hydrochloric acid, or when the tissue was first dropped into boiling water to arrest enzymic action, no darkening occurred and 3,4-dihydroxyphenylethylamine could be detected in normal quantity These observations provide confirmation that 3,4-dihydroxyphenylethylamine is the natural precursor of the black pigment observed in oxidized banana tissue

I wish to express my appreciation to Mr N W Simmonds for much helpful advice and for assistance in obtaining plant material for these and related studies

Lipase Activity in the Brown and Yellow Adipose Tissue of the Bat

OUR histochemical observations on the brown and yellow adipose tissue of the bat, *Hipposideros speoris*, showed that the activity of lipase is more or less the same in the two types of adipose tissue (unpublished) Fawcett[1], using histochemical methods, reported a much higher concentration of lipase in the brown than the yellow adipose tissue of the rat Here we report the results of a quantitative study of lipase activity in the brown and yellow adipose tissue of the bat, *Hipposideros speoris*

The enzyme material used was an aqueous extract of ether-defatted brown and yellow adipose tissue prepared in the following manner After decapitation, the subcutaneous interscapular brown adipose tissue and the yellow adipose tissue from the lower lateral sides of the abdomen were carefully removed and separately minced, defatted in two changes of ethyl ether at room temperature for 2 hr and dried in a vacuum desiccator at room temperature Extracts of the material were made by grinding with clean sand in cold distilled water in a test-tube for 1 hr and centrifuging at about 2,500 r p m for 5 min The supernatant was used for the study The method used for the assay was a manometric method adopted from Martin and Peers[2] using the Warburg apparatus, with a bicarbonate–carbon dioxide buffer system *p*H 7 4 at 37° C using tributyrin as substrate The reaction flask contained 1 5 ml of 0 025 *M* bicarbonate solution, 1 ml enzyme solution in the main chamber and 0 5 ml 4 per cent (v/v) tributyrin in 0 0148 *M* bicarbonate (emulsified by shaking with a drop of 'Tween 80') in the side arm, making a total volume of 3 ml The manometers and flasks were gassed for 3 min with a mixture of 95 per cent nitrogen and 5 per cent carbon dioxide from a cylinder After equilibration for 10 min the substrate was tipped in and two readings taken at intervals of 30 min The manometers were shaken at about 100 oscillations/min with an amplitude of 4–5 cm per oscillation

Lipase activity was calculated on the basis of the protein concentration of the enzyme solution used and is expressed as µl carbon dioxide produced/mgm protein/hr Protein was estimated by the micro-Kjeldahl method for total proteins[3]

Table 1 LIPASE ACTIVITY IN THE ADIPOSE TISSUES FROM ABOUT 35 BATS

Tissue	Lipase activity (μl CO_2/mgm protein/hr)
Brown adipose	30 45
Yellow adipose	37 85

From the results obtained it is evident that the yellow adipose tissue has a higher lipase activity than the brown, but at the same time the difference in concentration of the enzyme in the two types of adipose tissue is not sufficient to show a pronounced difference in histochemical preparations Among the other enzymes studied by histochemical methods (George and Eapen, unpublished) a distinct difference was observed only in the case of the dehydrogenases, such as succinic and lactic dehydrogenases, occurring in much higher concentrations in the brown than in the yellow adipose tissue Fat in the yellow adipose tissue is reported to be mobilized in greater concentration and at a faster rate than in the brown adipose tissue[4] This could be accounted for by the higher concentration of lipase in the yellow adipose tissue It may also be mentioned that the lipase activity in the pigeon adipose tissue is about six times greater than in the yellow adipose tissue in this bat[5]

'On'- and 'Off'-Responses of the Olfactory Epithelium

SLOW-action potentials have been found in various sensory receptors in response to adequate stimuli They were first found in the olfactory epithelium of a dog by Hosoya and Yoshida[1] Recently, Ottoson[2] studied them extensively in the olfactory epithelium of a frog He showed that the action potential is of a triangular shape, having a steeply rising limb, a round summit and a gradually falling limb in an exponential curve When the duration of the olfactory stimulus is long, a plateau appears in the middle of the falling limb and continues as long as the stimulation It is succeeded by an exponentially falling limb at the cessation of stimulation

In the course of our experiments on the olfactory epithelium of a frog and a toad, action potentials were frequently found at the cessation of stimulation Thus, two slow-action potentials appeared at the onset and the cessation of stimulation (Fig 1, *b*, *c* and *d*) These phenomena are well known in the retina[3], in the optic nerve[4] and in the auditory nerve[5] They are called 'on'- and 'off'- responses respectively It is interesting that similar phenomena were found in the olfactory epithelium as well

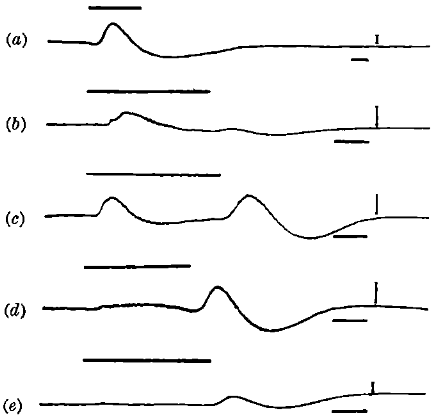

Fig 1 On- and off-responses (*a*), On-response (*b*), (*c*) and (*d*), Various types of on–off-responses The on-response is bigger than the off-response in (*b*) and vice versa in (*d*) (*e*), Off-response The horizontal lines above the potentials on the left indicate the durations of olfactory stimulation The vertical and horizontal bars on the right show 50 μV and 1 sec respectively

In order to study the stability of these response types, olfactory stimulation of the same odour and same intensity was repeated It was found that the shapes and magnitudes of the potentials varied from time to time An instance of such variability was shown in Fig 1, *b*, *c* and *d* The on-response is bigger than the off-response in Fig 1, *b*, but vice versa in Fig 1, *d* These differing results were obtained in the same epithelium by successive stimulation From these observations, it is supposed that the relation between the on- and off-responses is not simple and steady in the olfactory epithelium In a few cases only the off-responses appeared (Fig 1, *e*) Thus, in the olfactory epithelium of a frog and a toad, three types of responses, pure on-, pure off- and on–off-, were observed

The olfactory epithelium is a single cell layer, constituted by the olfactory and sustentacular cells arranged in parallel A synapse has not been found in the epithelium Consequently, it is supposed that these responses are produced by the activity of the olfactory cells Dogiel[6] and Jagadowski[7] described three types of receptor cell—one spindle shaped, one columnar and one conical Though these findings have not been confirmed by other histologists, it is presumed that there may be two or three types of the olfactory cells, corresponding to the on- and off-, or on-, off-, and on–off-responses

Detailed results and discussion will be published elsewhere

Synthesis of Diphosphopyridine Nucleotide from Nicotinamide by Slices of Liver

FOLLOWING the injection of nicotinamide, large increases in the diphosphopyridine nucleotide content of mouse tissues, particularly liver, have been reported by Kaplan and co-workers[1] Although it is thought that diphosphopyridine nucleotide is synthesized from adenine mononucleotide, the increase in the former is accompanied by an increase in the total acid-soluble adenine content of the liver

The present work shows that contrary to other reports[2] there is an increase in the content of diphosphopyridine nucleotide of rat and mouse liver incubated in oxygen *in vitro* in the presence of nicotinamide Three- to four-fold increases in content of diphosphopyridine nucleotide were obtained both *in vitro* in the presence of 10^{-2} *M* nicotinamide and *in vivo* after the injection of 500 mgm /kgm nicotinamide The levels of triphosphopyridine nucleotide were unaffected

In vitro the formation of diphosphopyridine nucleotide is at the expense of adenine mononucleotide (Table 1), as is to be expected if the former is formed from adenosine triphosphate and nicotinic acid or

Change		+ 1.71	+ 0.44	− 0.58	− 0.07

* Significantly different from corresponding control mean at $P < 0.001$.

Slices were weighed after freezing in liquid nitrogen following a 3-hr. incubation in Krebs–Ringer–phosphate medium in conventional Warburg apparatus. Gas phase oxygen, glucose 200 mgm. per cent. Nucleotides were separated and estimated using two-dimensional chromatography (*iso*butyric acid–ammonia and acetone–water systems) as previously described (ref. 7). Three approximately 100-mgm. slices were pooled for each determination and the nucleotides in the perchloric acid extract were adsorbed on to 50 mgm. 'Norit' columns.

Liver samples were quickly removed from decapitated rats 3 hr. after the intraperitoneal injection of nicotinamide, frozen in liquid nitrogen, and the nucleotides separated and estimated as above, using 150 mgm. 'Norit' columns. DPN, Diphosphopyridine nucleotide; AMP, ADP and ATP, adenosine mono-, di- and tri-phosphate.

nicotinamide mononucleotides[3,4]. *In vivo* the total adenine nucleotide concentration rises. It is clear that liver slices cannot replace the adenine mononucleotide used in this synthesis as readily as the intact liver.

Mouse liver slices behaved similarly, twofold increases in diphosphopyridine nucleotide being obtained.

Chromatograms of the nucleotides in rat and mouse liver slices after incubation with nicotinamide, and in liver of both species after the injection of nicotinamide, showed the presence of an ultra-violet-absorbing spot not present in the controls. The compound has been identified on the following grounds as the nicotinic acid analogue of diphosphopyridine nucleotide: (1) The appearance of a peak at 315 mµ in the absorption curve following the addition of potassium cyanide. (2) A phosphorus to adenine to ribose ratio of 2 : 1 : 2. (3) The electrophoretic pattern of the new compound after alkaline hydrolysis differed from that of similarly treated diphosphopyridine nucleotide only in the presence of a compound migrating with nicotinic acid and the absence of nicotinamide. (4) The compound co-chromatographed with the synthetic nicotinic acid analogue in the two-dimensional system used. (5) The compound and the synthetic analogue were not reduced by alcohol dehydrogenase, thus distinguishing them from diphosphopyridine nucleotide. The incorporation of nicotinic acid labelled with carbon-14 into diphosphopyridine nucleotide by human erythrocytes[5] and the synthesis of the nicotinic acid analogue by mouse liver[6] suggested that nicotinic acid itself might be utilized by liver slices for the synthesis of diphosphopyridine nucleotide. However, the incubation of rat liver slices in the presence of 10^{-2} M nicotinic acid did not lead to the formation of diphosphopyridine nucleotide or its nicotinic acid analogue. Kaplan has shown *in vivo* also that nicotinic acid does not markedly increase the level of diphosphopyridine nucleotide.

On the addition of phosphorus-32 to the incubation medium containing 10^{-2} M nicotinamide and rat liver slices the nicotinic acid analogue had a much higher specific activity than the diphosphopyridine nucleotide, suggesting that it was a precursor and not a breakdown product of the latter (Table 2).

Table 2. THE INCORPORATION OF PHOSPHORUS-32 INTO DIPHOSPHOPYRIDINE NUCLEOTIDE AND ITS NICOTINIC ACID ANALOGUE *in vitro*

	Specific activity (counts/min./mgm./P)
Diphosphopyridine nucleotide	14,700
Nicotinic acid analogue	65,700

Slices were incubated as in Table 1. 10 µc. phosphorus-32 added from side arm after 2-hr. incubation.

These results are consistent with current ideas[3] that nicotinic acid mono- and di-nucleotides are intermediates in the biosynthesis of diphosphopyridine nucleotide but do not explain why nicotinic acid does not lead to increased levels of diphosphopyridine nucleotide following incubation of slices or injection *in vivo*.

I wish to thank Prof. N. O. Kaplan for supplying the synthetic diphosphopyridine nucleotide analogue and Mr. R. Manston for skilled technical assistance.

Increased Circulating Insulin-like Activity in Obese-Hyperglycæmic Mice

THE hereditary obese-hyperglycæmic syndrome of mice is a condition characterized by extreme adiposity, hyperglycæmia, hypercholesterolæmia, and a variety of metabolic, endocrine, enzymatic and behavioural idiosyncrasies[1-3]. High blood glucose values are observed under conditions of *ad libitum* feeding in spite of an increased insulin content of the pancreas, extensive hypertrophy of the islets of Langerhans and marked hyperplasia and degranulation of the beta-cells[4].

The availability of the bioassay recently developed by Martin *et al.*[5] offered an opportunity to compare the insulin-like activity in the serum of obese-hyperglycæmic mice and their lean litter-mates, both in fed and fasted states. This bioassay is based on the observation that insulin increases the *in vitro* oxidation of glucose-1-^{14}C by rat epididymal fat, there existing a satisfactory linear correlation between the square root of this effect and the logarithm of the insulin-level[6]. 133 three months old adult mice and

Table 1 Circulating Insulin-like Activity in Obese-Hyperglycæmic Mice and their Non-obese Litter-mates

Experimental series	Slope of response log dose line	Type and status of animals*	Obese				Non-obese			
			Number and sex	Average weight (gm)	Serum glucose (mgm / 100 ml)	Serum insulin-like activity (μunits/ml.)	Number and sex	Average weight (gm)	Serum glucose (mgm / 100 ml)	Serum insulin-like activity (μunits/ml)
1	0 71	Adult Fed	25 (17 M + 8 F)	54	263	$\gg$ 1,000‡	20 F	27	93	107
2	1 27	Adult Fed	21 (11 M + 10 F)	58	198	> 1,000	20 M	25	98	33
3	2 21	Adult Fasted†	19 (10 M + 9 F)	56	70	690	29 F	26	64	114
4	1 52	Ageing Fed	21 (14 M + 7 F)	59	511	87	32 M	32	84	485

* Adult animals are 3 months old , ageing animals are 14 months old (the obese had been reduced and re-fed twice)

† Fasted animals have been deprived of food for 24 hr

‡ The sign $\gg$ indicates that the activity was considerably above 1,000 μunits/ml

53 fourteen months old ageing mice were used Body-weights were 54–59 gm for the obese mice and 25–32 gm for the non-obese The 21 ageing obese mice had been previously subjected to a regimen of alternating undernutrition (and weight loss) and *ad libitum* refeeding (and weight gain) It has been shown[7] that the life expectancy of such animals is shorter than that of animals allowed to gain weight without interruption

1-ml individual blood samples were drawn under light 'Nembutal' anæsthesia from the vena cava or the main thoracic vessels and rapidly centrifuged After a few severely hæmolysed samples had been discarded, the sera were pooled and stored overnight at 5° C Serum glucose was determined by the method of Somogyi–Nelson[8]

For each bioassay, the subdivided epididymal fat pads of 3 test rats (200–250 gm Wistar males) were incubated with 2 ml pooled serum or recrystallized insulin (Eli Lilly batch 366368) diluted serially down to 1,000 and 62 μunits/ml with Krebs–Ringer bicarbonate buffer with 2 mgm /ml gelatin added The glucose concentration of both buffers and sera was made up to 3 mgm /ml containing glucose-1-^{14}C (0 2 μc per flask) In the case of the ageing obese mice the high serum glucose was left unchanged except for the addition of labelled glucose The temperature in the Dubnoff incubator was 37 6° C and the duration of incubation 2 hr The rather wide range of insulin-like activities in the pooled sera (Table 1) was probably due to the variability of whole batches of mice and to that of the test rats, the epididymal fat of which was used for the bioassay However, the bioassays of sera of obese and non-obese mice were always run in parallel, and with this in mind, the results of the comparisons between obese and non-obese animals within the framework of each series appear highly significant (Table 1)

Obese mice (except extremely aged animals) exhibited a higher circulating insulin-like activity than non-obese This relationship held for fasted as well as for fed mice Only in the ageing obese mice with high serum glucose was circulating insulin-like activity lower than in the non-obese animals of the same age

It thus appears that the increase in circulating insulin-like activity in the obese-hyperglycæmic mice previously postulated on the basis of increased insulin content and histological aspect of the pancreas has been confirmed[4] The hyperglycæmia in these animals is thus not due to a primary lack of insulin-like activity in the blood as is the case in totally depancreatized dogs and cats and probably in young diabetics who require insulin for survival It seems analogous to untreated obese maturity-onset diabetes without ketonuria, shown to be associated with near-normal concentrations of insulin in the pancreas and probably near-normal fasting insulin-like activity in the blood, increasing after oral glucose The results also suggest that ageing animals may show a transition from the obese-hyperglycæmic syndrome toward insulin depletion and that diabetes *per se* may be one of the causes of their premature death

Effect of Polyphloretin Phosphate on the Suspension Stability of Red Blood Corpuscles

Polyphloretin phosphate belongs to a group of enzyme inhibitors of relatively high molecular weight synthesized a few years ago[1] By phosphorylation of phloretin—the aglucon of phlorizin—with phosphorus oxychloride under specific conditions a polymerization reaction occurred leading to a presumably cross-linked high-weight polymer

This compound, which does not dialyse through a 'Cellophane' membrane, has a strong electronegative charge and has been shown by ultracentrifugation to have a molecular weight of about

Table 1

Type of blood sample	Anticoagulant (*C*, sodium citrate, *H*, heparin)	Erythrocyte sedimentation rate

Horse (normal)	*H*	60	92			11	87			2	3

25,000 It was soon discovered that polyphloretin phosphate was a very strong inhibitor of various enzymes, for example, hyaluronidase Further investigations have shown that polyphloretin phosphate has several biological effects[2,3] It decreases the permeability of serous membranes such as the peritoneum and the pleura, when employed locally Recently, a general effect on the capillary permeability was established as polyphloretin phosphate was effective in preventing experimental œdemas in rats and guinea pigs[4] Investigations concerning the eventual effect of polyphloretin phosphate on the œdema in experimental burns are going on[5] During this investigation it was noted that those animals, which had received polyphloretin phosphate, did not show any, or but a minimal, sedimentation of their red blood corpuscles, as distinct from the controls This effect gradually diminished but was again evident after a new intravenous injection of polyphloretin phosphate Numerous investigations have shown[6,7] that high erythrocyte sedimentation rate is the result of intravascular aggregation of erythrocytes

Preliminary studies *in vitro* of this disaggregating effect have shown that very small amounts of polyphloretin phosphate (0 1–0 3 per cent) added to the blood of human subjects with high erythrocytic sedimentation rates more or less totally reduces this (Table 1) Presumably this effect is connected with the negative electrical charge of polyphloretin phosphate The blood plasma, including the plasma coating on the surfaces of the red corpuscles, will be electrically charged, whereby the latter repel each other This observation, which will be further studied, may be of practical value as it is well known that many pathological conditions are associated with intravascular erythrocyte-aggregation which reduces the circulating red cell volume and thereby the oxygenation of various organs A practically serviceable disaggregating drug has long been looked for, and as polyphloretin phosphate has a low toxicity and is already in clinical use on other indications it is hoped that forthcoming investigations will prove it useful to combat intravascular aggregation in human subjects

A Rapid Method for studying Tumour Blood Supply using Systemic Dyes

THIS communication describes a method for making visible those regions of solid malignant tumours supplied with flowing blood, if necessary, within a few seconds We have found that the blood in the interior of many tumours is not in communication with the circulation, and that the only part of such tumours which receives flowing blood is a thin layer at the periphery, varying in thickness from a few millimetres to, in extreme cases, less than 0 1 mm

Numerous investigations of tumour vascularity have been made by the injection of various substances such as oil, indian ink and radio-opaque material[1,2] into the vessels However, all these produce physiological changes such as spasms in the vessels, they are laborious, and they are quite unsuitable for systemic use on the living animal. So far as these go, our present results are consistent with them A number of earlier workers have injected vital dyes for different purposes and recorded the late cellular uptake[2,3], but did not mention the immediate intravascular distribution of dye Our method uses a high concentration of the triphenylmethane dye lissamine green (Gurr , Soc Dyers and Colourists Colour Index No 737) in the blood, which remains deep green for about 1 hr and turns the whole animal green, except where there are barriers The dye appears to be non-toxic, and is eliminated in the urine and bile within 24 hr , and mice survived indefinitely after an intravenous injection of 20 mgm of the dye (1 ml of a 2 per cent dye solution in Ringer solution)—enough to give momentarily a blood concentration of 0 5 per cent and an average body concentration of 0 1 per cent in a 20-gm mouse Tests showed that the dye was not decolorized by the tumour Lissamine green was chosen because it had been previously found by Goldacre (unpublished work, 1955) not to penetrate the living cell membranes and to be particularly suitable as a test for death in individual cells, being less toxic than trypan blue It was hoped to mark out the necrotic regions of the tumour with this dye , if the dye reached all parts of the tumour the necrotic regions would become deeply stained, and the living regions unstained, as happens with the corresponding cell suspensions *in vitro* Instead, most of the tumours remained white, except for a green peripheral layer The surrounding tissues became green, due to the green blood in them and green interstitial fluid derived from the blood

The supposed superior vascularization of tumours over the surrounding tissues has been remarked on by many authors[4–9] The vigorous new vascular proliferation which occurs at the edge of rapidly growing tumours is eventually appropriated by the infiltrating tumour; what happens to the captured vessels is not always made clear, though Ide *et al.*[9] have observed, through a transparent window, a fading away of vessels in the tumour centre, and Ribbert[5], Apolant[6], Gierke[7], Goldman[1] and Ewing[10] remark that blood-filled cysts, cul-de-sacs, blood sinuses, aneurism-like structures and obstructive arterial changes are a feature of some tumours.

Table 1 shows the extent of the blood circulation in 73 tumours of various kinds, based on inspection of the dissected tumours a few minutes after 0.5 ml. of 2 per cent lissamine green solution had been injected into the tail vein of the mouse, or 1 hr. after 1 ml. had been injected intraperitoneally (for rats eight times as much of the dye solution was used); similar results were obtained with both methods. It appears that about 10–12 days following transplantation of the four types of tumour mentioned, that is, when the tumours are about 1–3 cm. across, vascular obstruction occurs, confining the flowing blood to a thin surface layer of the tumour. Extensive regions not supplied with flowing blood, with a thin coating layer supplied with blood, were also found in various large spontaneous and methylcholanthrene-induced tumours of indeterminate age. Throughout the remainder of such a tumour it was striking to find vessels containing bright red blood with microscopically intact red cells, though the blood in the rest of the body was green; if the tumour was cut across (when the mouse was kept alive under anæsthesia) it scarcely bled at all, except at the periphery. Also noteworthy is the well-known difficulty of washing blood out of tumours by perfusion. Similarly, dye injected into the centre of such a tumour was still present, sharply defined along the needle track, 24 hr. later, whereas if injected into muscle it was rapidly dispersed.

The only other parts of an injected mouse which were not green were the brain, the interior of the eye, the material on the fœtal side of the placenta (if the mouse was pregnant) and to a large extent the testis, ovary and adrenal gland. There did not seem to be a blood-tumour barrier comparable with the blood-brain barrier, since a similar distribution in the tumour was found whether the dye injected was a weak or strong acid or base, or uncharged, or had large or small molecules; but some, such as neutral red and methylene blue, entered the brain.

Table 1

Tumour	Age, in days, of tumours appearing in lissamine green test as		
	All green	Thick green periphery, small white centre	Thin green periphery, large white centre
Sarcoma 37	6	11, 14	12*, 12*, 18, 20*, 21*, 21, 25, 25, 32* *R*, 32 *R*, 33 *R*, 33, 42* *R*
Mammary carcinoma	6	10, 14, 14, 14, 15	13, 13, 13, 13* *R*, 14, 14, 14*, 14*, 14*, 14*, 15, 15, 15*, 15*, 18, 18, 19, 19, 20, 20, 20, 24, 34*, 42 *R*, 42 *R*
Ehrlich Landschutz	7, 8, 12, 12	6, 10, 12	11, 13*, 14*, 16, 18, 18, 18, 32, 32, 32, 36, 36
Walker (rats)		5†, 10, 10, 11, 13	7†, 11, 14, 14

* In these tumours the green region was less than 0.5 mm. thick over most of the surface (measured with the optical micrometer), that is, 16 out of 52 tumours in the appropriate age-group had only a paper-thin covering of tumour tissue with effective access to flowing blood. *R* indicates a regressing tumour.

† Rapidly growing Chester Beatty strain; the remaining Walker tumours were slower-growing transplants into a Stockholm strain of rats.

This vascular obstruction, affecting the bulk of each medium-sized and large malignant tumour, seems to have important bearings on tumour biochemistry and physiology. Previous ultra-violet absorption data[11], and more recent enzymatic observations on transplanted tumours[12], have shown that we have to consider two main types of cell: one is the young growing and multiplying cancer cell at the extreme periphery of solid tumours and tumour cords, the other is a much larger cell typical of central but still vital tumour zones. The latter is poor in cytoplasmic nucleic acids and also in enzymic activity, which perhaps to some extent could be due to oxygen deficiency and lack of nutrition. The observed regional heterogeneity of tumour cells together with the irregular vascular pattern of tumours will thus more or less affect the interpretation of biochemical and isotope-incorporation observations obtained at the usual macroscale. Further, it seems apparent that the lack of blood flow in the bulk of tumours may affect some attempts at immuno- and chemo-therapy of solid tumours. Tumour cells on the inner edge of the green region would be exposed to a lower concentration of antibodies and chemotherapeutic agents than the normal tissue cells. Cells dissected out from the non-coloured tumour region were found to be dead, since they were instantly stained with lissamine green, except when within about 300µ from the green region, where mixtures of living and dead cells were found. These implications will be discussed in a subsequent paper.

We wish to thank Prof. Alexander Haddow and Dr. L. Révész for kindly providing some tumour-bearing animals. The investigation has been supported by institutional grants from the Jubilee Fund of King Gustaf V, the Swedish Cancer Society, and the Jane Coffin Childs Memorial Fund.

Electron Microscopical Structure of the Wall of Small Blood Vessels in Human Multiform Glioblastoma

WHILE using the electron microscope to study the fine structure of the small vessels surrounding central necroses, typical of multiform glioblastoma, endothelial proliferation and the presence of processes arising from the 'basement membrane' were observed. The fine structure of the latter differed essentially from that in normal vessels. The present observations are in accordance with earlier light microscopical observations[1,2].

The material used consisted of four cases of multiform glioblastoma and three cases yielding tissue of origin, namely, normal brain tissue. Specimens were fixed in osmic acid, and embedded in methacrylate. Ultra-thin sections were examined with a Philips *EM* 100 *B* electron microscope.

The structure of the basement membrane of the blood vessels in multiform glioblastomas (Fig. 3) differed from normal basement membrane (Fig. 1) in that it exhibited considerable variations in thickness, which was in the range 300–2500 A., and had a relatively irregular outline forming numerous branches extending deeply into and between the endothelial cells. The laminar structure of the basement membrane of the capillaries was largely dissolved. The basement membrane of the venules and arterioles showed similar alterations. In the wall of the latter the collagen fibres appeared to be detached from the elastic framework, so that the whole elastica interna exhibited an extremely loose structure; at certain places the basement membrane was very thin and incomplete and the endothelium consequently stretched (Fig. 4).

The blood capillaries in multiform glioblastoma were generally characterized by a high degree of endothelial proliferation. The size of the nuclei and the amount of cytoplasm were increased (Fig. 2), as compared with capillaries of normal brain tissue. Furthermore, in some instances the lumen was completely filled with endothelial cells. The endothelial layers appeared to be continuous. Frequently the mitochondria in the endothelium were so densely packed that they were separated from each other only by thin membranes. The presence of processes with a layered structure in the endothelium and in part also between the endothelial cells was particularly striking where marked proliferation of the endothelial cells occurred, but less conspicuous elsewhere. The present findings seem to indicate that the intra-endothelial collagen does not originate in the endothelial cells, but in the external layers: the basement membrane or the elastica interna. The cells in the endothelial proliferation appeared to have lost their polarity. When the lumen became markedly narrow or totally occluded, the augmented pressure in the blood-vessel may have resulted in dilatation of the vessel on the proximal side of the occlusion, that is to say, on the side of the inflowing blood-stream, where the basement membrane or the elastica interna already was defective. This appears to be the mechanism in the development of irregularities and especially of the numerous small aneurysms characteristic of multiform glioblastomas.

Some of the cells in the pericapillary region were in intimate contact with the capillary walls through organelles resembling the Golgi apparatus. In these sites the basement membrane showed a more reticular structure. In close vicinity to the capillaries, between them and the necroses, numerous erythrocytes and lymphocytes with granular cytoplasm were seen, a finding often reported in conventional microscopic investigations of glioblastomas. In contrast to the capillaries in normal brain tissue, a large part of the capillaries of glioblastomas had a pericapillary zone of lower density.

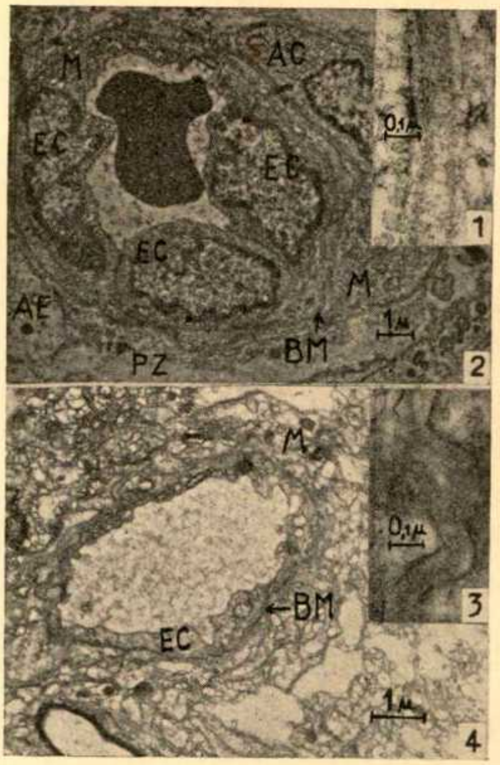

Fig. 1. Basement membrane (*BM*) of blood vessel in normal brain tissue. A longitudinal layer in the margins and a radially organized lamellar structure in the middle. × 45,000

Fig. 2. Hypertrophy and proliferation of endothelial cells (*EC*) in capillary wall of a glioblastoma. Pericapillary zone (*PZ*). Left: mitochondria (*M*) at the margin of an astrocytic end-foot (*AE*). Right: an 'additional cell' (*AC*). × 5,000

Fig. 3. *BM* of a capillary in a glioblastoma. Irregular outline and varying diameters. The structure is more vesicular than lamellar (cf. Fig. 1). × 45,000

Fig. 4. Capillary with an extremely thin and incompletely developed *BM*. × 7,400

The electron micrographs of normal vessels (controls) confirmed previous observations. In addition, the present findings of the structure of the normal basement membrane were corroborated by polarization microscopic observations[3].

Further results will be published later in another connexion, with special reference to the fine structure of the wall of the small vessels in other gliomas and in metastatic tumours.

Potentiation of Contractions after Rest in the Isolated Rat Ventricle Preparation

Post-rest potentiation describes the transient increase in the amplitude of contractions which occurs after a short period of rest in heart muscle.

This communication describes factors which influence the production of this augmented response in the electrically stimulated rat ventricle preparation; particularly some variations of the ionic composition of the medium.

The degree of potentiation was determined by measuring the amplitude of the first augmented response after the rest period, and expressing this as a percentage of the amplitude of the steady-state contractions (12/min.) preceding the rest period. Many modifications of the basic medium[1] were made, some of which necessitated changes in total ionic strength. Tonicity, however, was controlled with sucrose.

The degree of potentiation was found to increase when the rest period between two contractions was increased (see Fig. 1). This finding is in accord with the decrease of the contraction amplitude in response to an increase of the stimulation frequency. It follows that the steepness of the 'negative staircase' is proportional to the frequency after the rest pause.

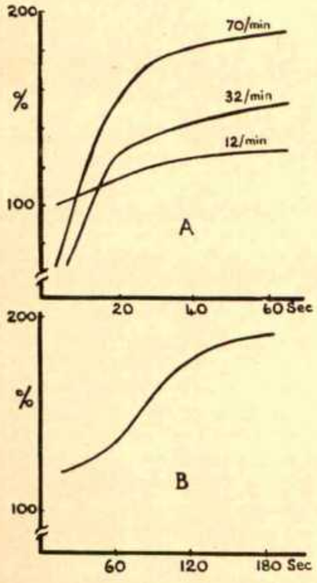

Fig. 1. Graphs plotting the degree of post-stimulation potentiation against: (*A*) duration of rest period; three frequencies of stimulation during the 2-min. conditioning periods are compared; (*B*) duration of the conditioning or 'work' period; stimulation frequency, 70/min. during the conditioning period; rest pause, 1 min.

An augmented contraction response followed by contractions of decreasing amplitude was produced after rest at all temperatures over the range 22–38° C. (compare Katzung and Farah[2]). A reversal of the 'staircase effect' could not be produced after rest by varying the temperature or by varying the calcium concentration. This is in contrast to the findings in turtle heart[2] and frog heart[3].

Conditioning periods of increased activity have been reported to alter the degree of potentiation[4]. This relationship between previous activity and potentiation has been confirmed (Fig. 1). The degree of potentiation after a rest pause has been found to be related to (*a*) the duration of the rest pause, (*b*) the frequency of stimulation preceding the rest pause, and (*c*) the duration of the period of stimulation preceding the rest pause.

Table 1

Medium	Effect on steady-state contractions (per cent)	Effect on potentiated contractions
8·8 m*M* KCl	+ 20	slight increase*
10·0 m*M* KCl	none	none
2·95 m*M* KCl	−20 to −35	slight decrease* (in contrast to increase noted by Penna and Garb (ref. 5))
7·8 m*M* $CaCl_2$	up to + 90	marked decrease or abolition
1·3 m*M* $CaCl_2$	−60	slight increase* (confirms Penna and Garb (ref. 5))
180 m*M* Na^+	−25 to −35	slight increase*
93 m*M* Na^+	+ 40	decrease or abolition (see Fig. 2)
80 m*M* Na^+	none	abolition

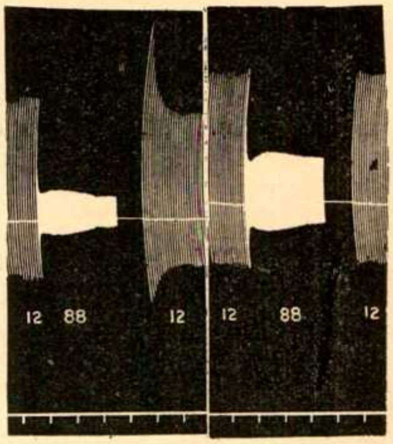
* Differences between potentiation in Krebs's medium and in experimental medium not statistically significant.

In contrast to several reports, it was found that a single extra systole or premature contraction did not induce further potentiation after a rest pause. These contradictory findings might be explained by variations in the composition of the media.

Analysis of the isometric twitches occurring during the 'negative staircase' suggests that prolongation of the active state is not the cause of potentiation after rest in the rat ventricle preparation. Acetylcholine, eserine and atropine were without effect upon both potentiated and steady-state contractions.

The influence of ions upon the potentiation of contractions is summarized in Table 1. Although decreasing the sodium or increasing the calcium concentrations in the medium produces an increase in the amplitude of steady-state contractions of heart muscle, it has now been shown that such ionic alterations also markedly reduce or even abolish the potentiation of contractions after rest. This finding lends support to the view that "the augmentation process differs fundamentally from the regular contractile process"[5].

The experimental results support the suggestion that the accumulation of a hypothetical 'potentiating



145 m*M* Na^+ 93 m*M* Na^+

Fig. 2. Records showing the absence of post-stimulation potentiation in 'low NaCl' medium. Stimulation frequencies per min. during conditioning periods are marked. Time intervals, 1 min.

substance' (hexose monophosphate[6] or noradrenaline[7]) is responsible for potentiation of contractions[2,4]. Since ionic changes are known to occur and remain for some time within muscle cells as a consequence of increased activity, these might influence cellular metabolism at the enzyme level or might act at specific sites on the cell membrane, and thus bring about, either directly or indirectly, potentiation of contractions. In the presence of a reduced external concentration of sodium or increased calcium, the ionic conditions necessary for the production of the potentiation are not present.

Positive Inotropic Activity of Cytidine Triphosphate

Although nucleotides other than those of adenyl origin have been isolated from muscle[1], physiologists, when considering the events associated with the contraction-relaxation cycle, have assigned a dominant role to the adenosine derivatives—in particular to adenosine triphosphate[2]. It was therefore interesting to note that cytidine triphosphate exerted a marked positive inotropic action on isolated perfused toad hearts.

A perfusion apparatus and experimental technique, developed to record continuously the metabolic and physiological changes associated with drug action on the spontaneously beating toad heart (*Bufo marinus*), have been described previously[3]. In this study the apparatus was used without modification and the observations described were obtained from a series of eight hearts perfused at 25·0° C. before and following the addition of cytidine triphosphate (sodium salt) to give a final concentration of 10 µgm./ml. The gaseous medium was oxygen, and observations of beat-rate, drops per beat, maximum aortic pressure and rate of oxygen uptake were recorded at 15-min. intervals, except during that period immediately following the addition of cytidine triphosphate, when 3-min. observations were made.

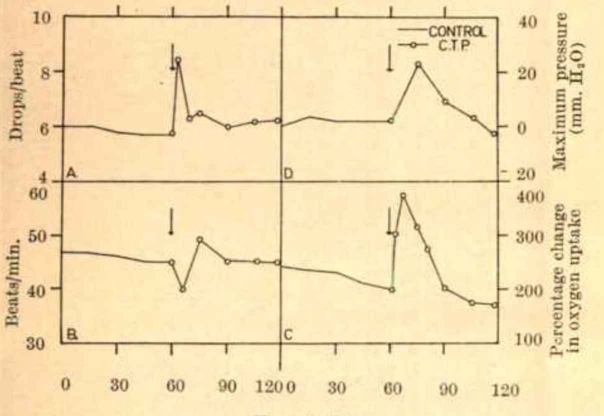

Fig. 1. Effect of cytidine triphosphate (10 µgm./ml. final concentration) on drops ejected per beat (1*A*), beats per min. (1*B*), maximum aortic pressure (1*C*) and oxygen uptake (1*D*) of the isolated heart. Mean results of eight experiments are displayed and cytidine triphosphate added at the arrow

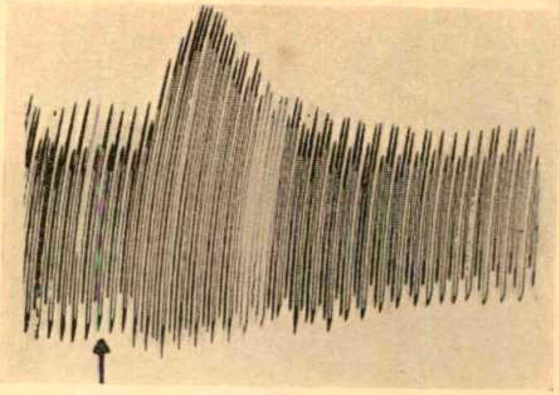

Fig. 2. Kymograph record showing positive inotropic effect of cytidine triphosphate (10 µgm./ml. final concentration)

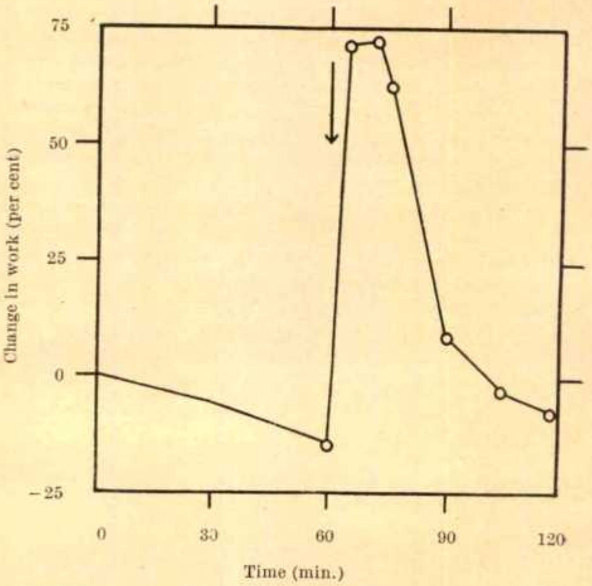
The results obtained are summarized in Figs. 1–4. In Fig. 1 it can be seen that cytidine triphosphate at the above concentration produced an increase in the number of drops per beat (Fig. 1*A*) which was associated with a raised maximum aortic pressure (Fig. 1*C*) and an augmented rate of oxidative metabolism (Fig. 1*D*). A transient bradycardia, followed by a slight tachycardia, accompanied these changes (Fig. 1*B*).

The increased maximum aortic pressure noted was paralleled by an augmented force of ventricular



———, Control; —○—, cytidine triphosphate

Fig. 3. Mean results of eight experiments showing effect of cytidine triphosphate (final concentration, 10 µgm./ml.) on useful work done by the heart. Cytidine triphosphate added at arrow

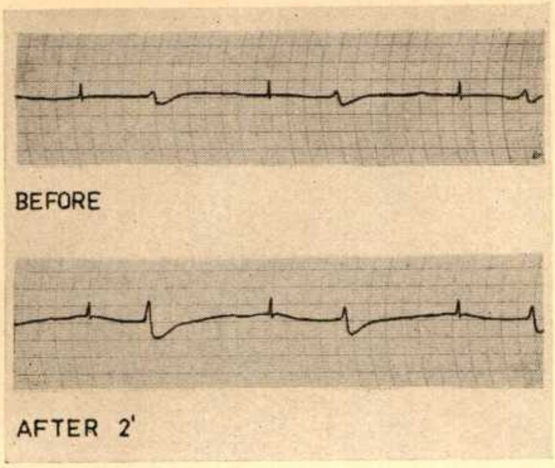


Fig. 4. Electrocardiograph tracing from perfused heart immediately before and 2 min. after addition of cytidine triphosphate (10 μgm./ml.). Note change in '*ST*' segment

contraction recorded by the conventional kymograph method (Fig. 2).

Correlation of the results shown in Fig. 1 provides an index of the useful work done by the heart, and in Fig. 3 it can be seen that cytidine triphosphate significantly increased this work-output-level.

In general, the positive inotropic effect of cytidine triphosphate described above resembles that previously recorded following the addition of glycosides and 9-α-fluorohydrocortisone to similar preparations[4,5]), for both involve increased work output levels associated with augmented rates of oxidative metabolism. This similarity raises the question as to whether nucleotides other than those of adenyl derivation are involved in the positive inotropic action of cardiac glycosides and whether or not these other nucleotides may play a part in the transfer of energy during normal contraction and relaxation.

The rapidity with which the effects of cytidine triphosphate appear and the deformation of the '*ST*' segment of the electrocardiograph which accompanies the response (Fig. 4) indicate the probability that surface activity is involved. Such a site of action may be linked with Kirschner's suggestion that phospholipids play a part in regulating ionic exchange rates across cell membranes[6,7], since cytidine-containing compounds are involved in the synthesis of phospholipids.

The expenses of this investigation were defrayed by a grant from the Life Insurance Medical Research Fund of Australia and New Zealand.

An Inhibitor of Cytochrome Oxidase Activity in the Sea Urchin Egg

Previous work in this laboratory[1,2] has demonstrated the presence of a highly active cytochrome oxidase in the isolated mitochondria of unfertilized sea urchin eggs. This activity is only 25 per cent lower than that of the mitochondria of the newly fertilized egg and up to the blastula stage[2]. No cytochrome oxidase activity has been found other than in the mitochondria[1,3]. On the other hand, it is known that the oxygen consumption of the unfertilized sea urchin egg is quite low; fertilization restores a normal respiratory level which increases continuously during the early development (for a discussion, see ref. 4). The suggestion was then made[2] that in the unfertilized egg an extra-mitochondrial respiratory inhibitor might be present which would be removed somehow upon fertilization.

In this communication we wish to report the results of experiments indicating the presence of an inhibitor of the cytochrome oxidase activity in the unfertilized egg.

Homogenates in sucrose or 0·01 *M* phosphate at *p*H 5·0 of unfertilized and fertilized jelly-free eggs of *Paracentrotus lividus* (freshly collected or lyophilized) were centrifuged at 12,000*g* for 10 min.; the supernatant was then centrifuged at 105,000*g* for 60 min. The inhibitory activity of the supernatant (called 'cytoplasmic supernatant') was assayed in a system as indicated in the legend of Fig. 1. Mitochondria were prepared from sucrose homogenates of unfertilized and fertilized eggs or from rat or mouse liver as described previously[2,5]. Since the inhibitory effect was manifested equally well on either sea urchin or mammalian mitochondria, the latter were then used routinely in our assays in order to have a more constant system. The cytochrome oxidase was assayed in a conventional Warburg apparatus[1,2].

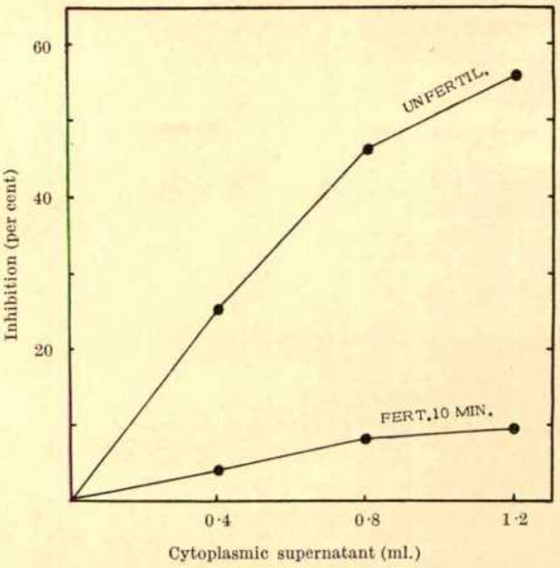

Fig. 1. Inhibitory effect of the cytoplasmic supernatant of unfertilized and fertilized eggs of *Paracentrotus lividus* on the cytochrome oxidase activity of mouse liver mitochondria. Each vessel contained in the final volume of 3·0 ml.: 0·2 ml. of mitochondria suspension; $2 \cdot 46 \times 10^{-5}$ *M* cytochrome *c*; 30 μ*M* sodium ascorbate; 0·033 *M* phosphate buffer *p*H 7·4; 0·2 *M* sucrose; cytoplasmic supernatant as indicated (in the present experiment both supernatants had a concentration of 1·35 mgm./nitrogen/ml.). Controls with cytoplasmic supernatant of mouse liver

Fig. 1 shows the striking inhibitory effect on the cytochrome oxidase activity of the cytoplasmic supernatant of unfertilized eggs, whereas in that prepared from eggs collected 10 min. after fertilization the inhibitory effect is much lower. In the cytoplasmic supernatant of eggs prepared 1 hr. after fertilization the inhibitory activity is negligible. After dialysis, the inhibitor has been quantitatively recovered in the dialysate (after concentration by lyophilization) thus indicating a low molecular compound. The inhibitor is quite stable in the acid-range (and, in fact, can be extracted fully active by 5 per cent trichloracetic or perchloric acid), whereas it is destroyed by alkalinization. The activity is almost completely abolished also by heating at 95° C. for 30 min. A preliminary purification of the inhibitor has been achieved by passing the crude concentrated dialysate at neutral pH through a 'Dowex 50' column in the ammonium-cycle. The inhibitor is thus quantitatively recovered in the effluent still contaminated by a few amino-acids but free of substances absorbing in the ultra-violet range between 250 and 280 mμ.

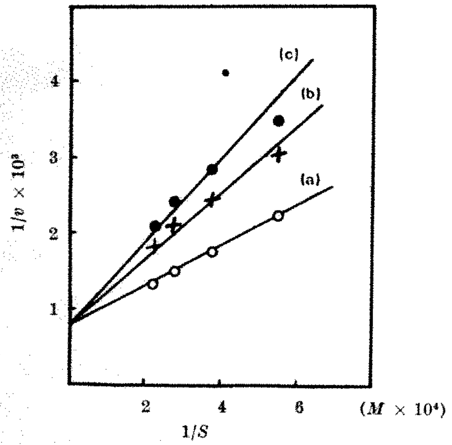

Fig. 2. A Lineweaver and Burk plot of $1/v$ (v, μl. oxygen/hr./mgm. protein) against $1/S$ (S, concentration of cytochrome c)). a, Control; b, with 0·25 ml. of inhibitor; c, with 0·5 ml. of inhibitor prepared as described in the text. Other conditions as in Fig. 1

Using this partially purified fraction we have obtained evidence for the competitive type of the inhibition, as is indicated in Fig. 2. Furthermore, spectrophotometric assays using isolated mitochondrial membranes[6] as a source of cytochrome oxidase suggest that the inhibitory action may affect the cytochrome oxidase itself. Work is in progress aiming at the identification and isolation of the inhibitor and examination of the process of its inactivation following fertilization.

This work has been supported by grants from the Rockefeller Foundation and the Consiglio Nazionale delle Ricerche.

Extended Dormancy of Deciduous Woody Plants treated in Autumn with Gibberellic Acid

WEAVER[1] has shown that autumnal application of gibberellin prolongs dormancy of *Vitis vinifera* shoots in the following spring. We[2] recently reported that application of gibberellic acid in late summer and autumn delayed leaf-fall of several woody species; further observations on these plants this spring have shown that in many of them dormancy was prolonged. Thus this unexpected response to gibberellins may not be uncommon.

In our experiments gibberellic acid was sprayed on as a 50 μgm./ml. aqueous soution. Fifteen weekly applications were made between mid-August and late November, 1958. Little or no after-effect was noticed when growth recommenced this spring in the following species: *Acer rubrum, Castanea sativa, Parthenocissus tricuspidata,* a *Rhododendron* × *molle* cultivar, *Taxodium distichum* and *Ulmus procera.* This list includes nearly all those species which showed no response in autumn to the gibberellic acid treatment but, in addition, two species where leaf-fall was delayed (*P. tricuspidata* and the *Rhododendron* hybrid) and the one species in which leaf-fall was accelerated (*T. distichum*).

Bud-break was delayed by 1–3 weeks in the following species: *Acer pseudoplatanus, Betula verrucosa, Fagus sylvatica, Fraxinus excelsior* and *Sorbus aucuparia.* Many buds and branch-tips of *B. verrucosa* were killed; we believe that this was due to frost damage of young growth induced by gibberellic acid in the previous autumn. In *Liriodendron tulipifera,* bud-break was more or less simultaneous on treated and untreated branches, but leaf-expansion was much slower on the treated branches.

The most striking effects were seen on *Prunus avium.* Here gibberellic acid had little effect on purely vegetative buds, but flower buds were profoundly affected. Most flower buds have remained completely dormant—indeed many are dead. Others have produced distorted or much-reduced flower clusters several weeks after untreated branches had flowered. On branches on the edge of the sprayed area, which probably received reduced doses of gibberellic acid as spray drift, flowering was delayed by about three weeks, though the flowers formed were in all other ways normal.

Of the species showing prolonged dormancy, one (*F. sylvatica*) showed no response to gibberellic acid in the previous autumn. Thus prolongation of dormancy is not necessarily a consequence of, or associated with, delayed onset of dormancy in the autumn. These results support Weaver's view[1] that properly chosen treatments with gibberellin in the autumn might usefully be employed to delay flowering in the following spring, in areas where frost damage is a hazard of fruit cultivation.

BIOLOGY

A Suspected Virus Disease of the Citrus Red Mite *Panonychus citri* (McG.)

A DISEASED condition of the citrus red mite, *Panonychus citri* (McG.), was first observed in material collected dear Oxnard, California, in 1958. Experimental proof that the disease was transmissible was obtained by two methods: first, by transferring healthy mites to lemons bearing a diseased culture, and secondly, by spraying an aqueous suspension, prepared from ground-up diseased mites, on to healthy mite colonies. In each case the healthy mites developed infection[1]. Many diseased mites become paralysed with the legs stiffened ventrally. Diarrhœa sometimes occurs and mites may be found dead with the anal end fixed to the feeding surface by fæcal material.

Since no disease agent visible by optical methods could be detected, an intensive study with the electron microscope was made on the assumption that a virus might be concerned.

At first, ultra-thin sections of diseased and healthy mites were examined without any conclusive results. The next attempt was to try to isolate a virus; aqueous suspensions of diseased mites were made and clarified by differential centrifugation, the final spins being made at 36,000 r.p.m. (110,000*g*) on a 'Spinco' centrifuge. From three separate suspensions of material which had proved infective, a characteristic, virus-like particle was observed. The results obtained from a similar suspension of healthy mites, treated in the same way, were quite different. Whereas in the case of the infective fluid, virus-like particles were present in large numbers in every grid square, suggesting at a rough calculation 5 million particles/ml., it took several hours of hard searching to find three or four similar particles in the control fluid. This may suggest the presence of a small quantity of latent virus infection in the healthy mites. In a second control suspension no virus particles could be observed.

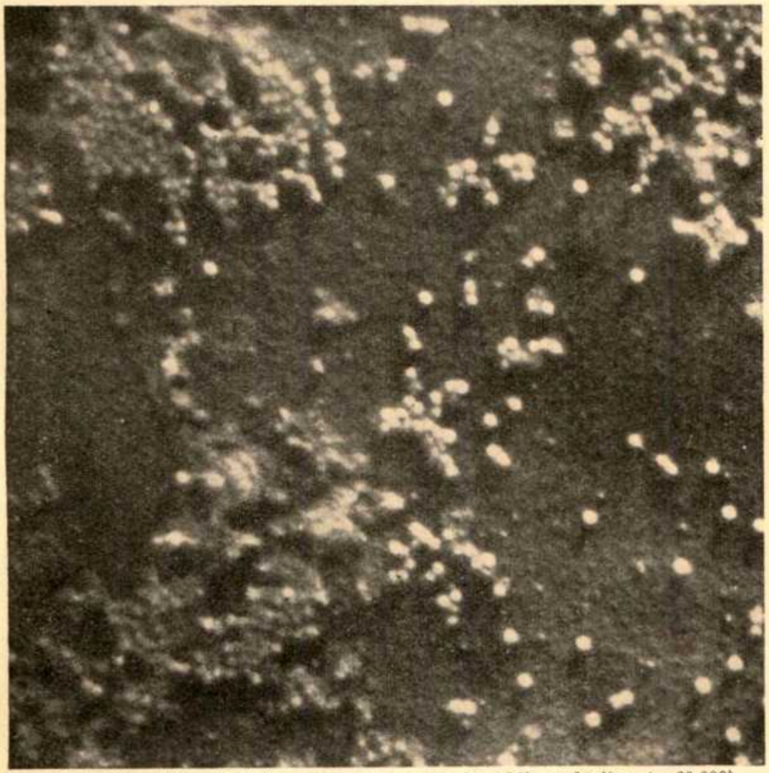

Fig. 1. Virus-like particles from an aqueous suspension of diseased mites. (× 60,000)

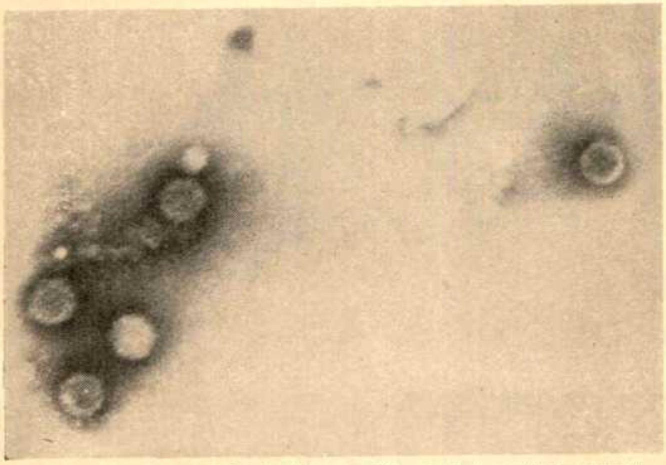

Fig. 2. Similar particles to those in Fig. 1, but negatively stained with phosphotungstic acid, adjusted to *p*H 7. The particles have a six-sided contour which suggests they may be icosahedra. The particles showing a darker centre are partially empty. (× 160,000)

Fig. 1 is an electron micrograph of the particles, shadowed with palladium gold; the particle is very small and measures about 35 millimicrons in diameter. The magnification is × 60,000. Fig. 2 shows similar particles stained with phosphotungstic acid at a magnification of × 160,000. Note the six-sided contour[2] and that four of the particles appear to be empty or partly empty[3].

This is the first record, so far as we are aware, of a virus disease in the Arachnida, and it suggests that viruses exist in other classes of organisms in which none has yet been discovered. That this disease might prove useful in the control of a serious citrus pest has already been indicated[1]. Whether it can be induced to attack other species of red spider (spider mites) in the United States or in Britain remains to be proved.

Stomach Contents of Spawning Quinnat Salmon

QUINNAT salmon (*Oncorhynchus tschawytscha*) normally spend up to a year after hatching in fresh water before migrating to sea as smolt. They stay at sea until mature, in three to four years time, then they usually cease feeding and migrate up the rivers to their spawning grounds. Quinnat salmon are reported to spawn once only, dying without feeding again after spawning.

On May 5, 1957, I assisted in the examination of some spawning quinnat salmon in the Harrison Bight Stream, a tributary of Lake Heron, New Zealand. L. Heron contains 'landlocked' quinnat salmon, but is also accessible to sea-run fish. Forty-three fish were examined, of which only four had anything in their stomachs. Of these four, one had some of the aquatic plant, *Potamogeton*, in its fore-stomach and the other three had each a young quinnat salmon.

The three which contained fish were spent dead males of 9½, 10 and 10¾ lb. weight. The lengths of the young quinnat salmon after preservation in formalin were 5·3, 6·3 and 6·9 in. These young fish were all males with hypertrophied testes, as shown in Fig. 1. There was little sign of digestion; two were slightly decomposed or digested in the head region, otherwise the skins were intact.

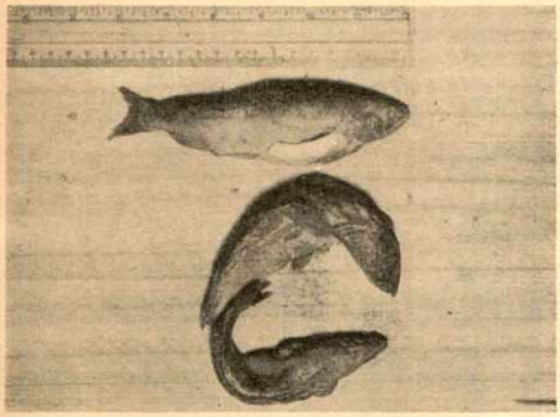

Fig. 1. Young quinnat salmon taken from stomachs of spawning quinnat salmon. Body-wall of top fish removed to show hypertrophied testes

One of the young quinnat salmon contained ten quinnat salmon eggs in its stomach, the others contained insect remains.

Dominance and hierarchy formation have been observed in groups of most salmonids[1]. Movements involved in feeding and in aggressive nipping by quinnat salmon are almost identical[2]. Also it is known that vigorous chasing between quinnat salmon occurs on the spawning redds. Hence, it is suggested that the young quinnat salmon were swallowed while being chased away from the redds by the larger fish.

The fact that the young fish appeared to have been feeding normally suggests that fasting and sexual maturity are not necessarily concomitant in male quinnat salmon.

Thanks are due to Prof. E. Percival for his advice.

Local Races in Lugworms (*Arenicola marina* (L.))

THE spawning of *Arenicola marina* (L.) on the shores of the British Isles occurs during the last three months of the year, but within these limits there are striking variations of spawning time from place to place. Each local population of lugworms appears to have a characteristic spawning period which occurs at much the same time every year (Duncan, *Proc. Zool. Soc.*, in the press). The differences in the dates of spawning may indicate a tendency towards genetic variation between different populations; they would also encourage such differentiation. There are, of course, environmental differences between beaches which may influence the time of spawning, but it is difficult in this way both to account for the observed similarity of the spawning periods of lugworms at Dale Fort, Wales, and Whitstable, Kent, and for the fortnight's difference in the spawning of worms living as close together as Port St. Mary and Derbyhaven in the Isle of Man.

Lugworms are sedentary animals which spend most of their lives in their burrows. They are capable of swimming, and previous records of lugworms seen or caught in the sea[1] or of beaches emptied of lugworms being re-populated in a short time[2,3] suggest that they carry out migrations, particularly in winter[4], away from the colder, higher-lying parts of the beach and in the spring[5] which may be a dispersal movement. Such journeys are likely to be confined to their own or adjacent beaches unless there are strong tidal currents along the coast flowing close inshore. The fertilized egg sinks in sea water and the larva lives on the surface of the sand attached to sand grains; there are therefore no special provisions for widespread dispersal. Lugworms are not restricted to the littoral, but how far seawards they extend is not known. Often a change from sandy to rocky terrain limits the seaward distribution, but where a sandy bottom links two apparently separated sandy shores, it is possible that a sub-littoral stock may connect the two populations, and it appears likely that the lugworms of the British Isles exist in many nearly isolated populations, with only slight possibilities of interbreeding. Such a situation is clearly conducive to producing differentiated local races. It may therefore be of interest to note the following differences between populations in characters other than spawning period, which were observed in the course of my work.

The mean sizes of the spawning adults from different populations are given in Table 1 and show a very wide range, that for Llanfairfechan being eight times greater than that for Cullercoats. The spawning samples also showed considerable differences in their colour (Table 1). Apart from a tendency to darken with increase in size and age, the causes of these colour differences, whether environmental, physiological or genetical, are not known. There is a very small difference in the size of ripe cœlomic germ cells from lugworms of different localities (Table 1). The difference appears to be a real one, particularly for the oocytes (90 per cent of the healthy oocytes from ripe females from Port St. Mary were 170μ in diameter and only 5 per cent either 180μ or 190μ). There is no correlation between the mean size of the worms and the size their germ cells usually attain, as one would expect to find if availability of food in different beaches was a determining factor. There appear to be differences in the age and size at which *Arenicola*

* The worms containing these germ cells were collected just before spawning and were preserved in 4 per cent formalin, so that the measurements are comparable.

larvæ from different localities attain certain stages in their development (Table 2). On the whole, larvæ from Kent and the Isle of Man take longer to attain each developmental stage and there is variation in the sizes of larvæ at the same stage in development. The initial size of the ripe oocyte perhaps influences the size of the developing larva. Moreover, there was a small anatomical difference : all larvæ from the Isle of Man older than 10 days after fertilization possessed a prototroch with both long and short cilia, whereas these cilia are of uniform length in Blegvad's and Newell's figures of Danish and Kentish larvæ.

The evidence just presented is perhaps not impressive as evidence for the existence of local races in *A. marina*. The differences in size of ripe germ cells in different populations is very small, the sizes and ages of Danish larvæ and those from the Isle of Man are based upon animals reared in the laboratory and not under normal conditions, and the effects of environmental factors such as availability and nature of food upon the size and colour of lugworms have not been studied. There are, however, other differences among various populations which may be significant. Wells[6] examined 94 anomalous specimens of *A. marina* collected by Ashworth between 1908 and 1930 from two widely separated localities, the Firth of Forth and the Firth of Clyde, and found considerable variation in several structural features ; in fact the structural variation was such that he states that "characters which distinguish *Arenicola glacialis* from typical *A. marina* appear to be such as might turn up in anomalous *A. marina*". He therefore proposes that *A. glacialis* be given subspecific status as *A. marina glacialis* Murdoch. For comparison, Wells examined in 1956 samples of the present-day populations of lugworms from these two localities, and found that about 4 per cent of the worms from the Firth of Clyde showed anomalies in segment number and about 20 per cent of the worms from the Firth of Forth showed reduction in the annulation between not only the second and third chætigerous segments but also between the third and fourth. Such reduced annulation of the anterior segments was also found in some of the littoral populations examined during the present work although in much smaller proportions (ref. 6, p. 403). Such structural differences, if genetic, would be likely to appear among populations isolated geographically and with different breeding periods.

Table 2. A COMPARISON OF THE AGES (IN DAYS AFTER FERTILIZATION) AND LENGTHS (IN MM.) OF FOUR LARVAL STAGES OF *Arenicola marina* IN DIFFERENT LOCALITIES

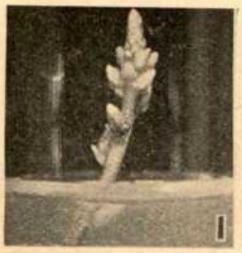
In vitro Culture of the Inflorescences, Flowers and Ovaries of an Apomict, *Aerva tomentosa* Forsk.

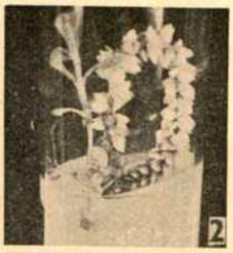
IN recent years several attempts have been made to culture the ovules[1] and ovaries[2] of some angiosperms. While there has been considerable success in raising viable seeds in test-tubes from normally fertilized ovaries[3], the results have not been so encouraging when unfertilized ovules[1,4] or ovaries are cultured. The present communication outlines the results of my experiments on an apomictic species, *Aerva tomentosa*[5].

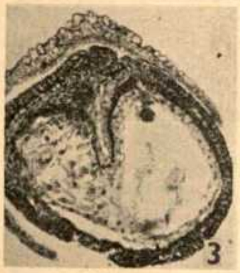
The plant is dioecious and male plants are extremely rare in Nature. The female flower possesses 5–8 perianth lobes enclosing a monocarpellary ovary and 8–10 staminodes.

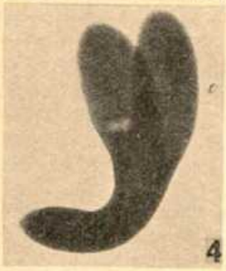
Three types of cultures were maintained : excised ovaries, flowers, and pieces of spikes. Nitsch's[6] medium was used with sucrose as a carbon source. This was also supplemented with vitamins and various growth substances.

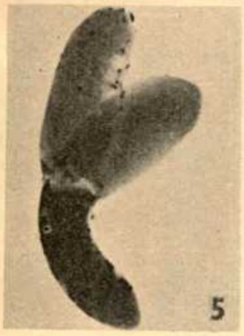
Ovaries (220μ in diameter) cultured at the megaspore mother cell stage in the basic medium yielded 20 per cent fruits. However, the fruits were smaller, being only 550μ in diameter as compared to the normal diameter of 1,100μ, and the seeds were abortive. Larger ovaries at the megaspore mother cell stage having a diameter of 440μ gave 40 per cent fruit set, but again the seeds were empty. On supplementing the basic medium with vitamins and glycine (supplemented medium) the fruit set increased to 50 per cent and the size was comparable to that attained *in vivo* (1,100μ), but only the seed coat developed normally and an embryo was absent. Gibberellin (10 p.p.m.) and indoleacetic acid (2 p.p.m.) either alone or in combination inhibited the growth of the ovaries and no fruits were obtained. In the supplemented medium to which kinetin (0·2 p.p.m.) and indoleacetic acid (2 p.p.m.) had been added, the











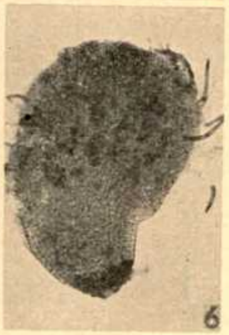


Fig. 1. Young spike after 3 days in supplemented medium + kinetin (0·2 p.p.m.) + indoleacetic acid (2 p.p.m.). No seeds were formed in such spikes. (× 0·7)

Fig. 2. Spike with open flowers inoculated in supplemented medium + yeast extract (500 p.p.m.) and photographed after 4 weeks. Seeds matured in many ovaries; one of the seeds has germinated *in situ*. (× 0·7)

Fig. 3. Longitudinal section of ovule showing globular embryo produced in 2 weeks from an open flower cultured on supplemented medium + yeast extract (1,000 p.p.m.). (× 32)

Fig. 4. Mature embryo from a flower attached to the plant; 2 weeks after the mature embryo sac stage. (× 18)

Fig. 5. An embryo dissected from a 4-week old spike inoculated at the mature embryo sac stage in supplemented medium (sucrose, 8 per cent). (× 21)

Fig. 6. A 4-week old embryo in supplemented medium + casein hydrolysate (200 p.p.m.) from a flower inoculated at the mature embryo sac stage. (× 20)

growth of the ovaries ceased after attaining a diameter of 550μ and the ovules failed to form the black seed coat.

In subsequent experiments ovaries were excised from open flowers (that is, at the mature embryo sac stage). When these were planted on supplemented medium and yeast extract (500 and 1,000 p.p.m.), a proembryo was formed; in very rare cases it developed up to the globular stage.

When whole flowers were cultured on supplemented medium, supplemented medium and yeast extract (1,000 p.p.m.) or supplemented medium and casein hydrolysate (200, 400 p.p.m.), 60 per cent of the ovaries grew into fruits; and 25 per cent of them gave viable seeds in about three weeks. In yeast extract (1,000 p.p.m.) a globular proembryo (Fig. 3) was formed in two weeks which took another week to mature. It was smaller than the embryos obtained from Nature which matured in only two weeks (Fig. 4). In supplemented medium and casein hydrolysate (200 p.p.m.) growth of the hypocotyl was arrested and the cotyledons were flap-like with numerous hairs (Fig. 6).

Next I attempted to rear young spikes (Fig. 1), but they never grew to maturity. However, spikes cultured at the time of the opening of flowers gave very encouraging results. Four concentrations of sucrose (2, 4, 6 and 8 per cent) were tried along with the supplemented medium. In these there was 40 per cent seed setting and the embryo was as large as or larger than that of plants growing in Nature (Fig. 5). With yeast extract (500, 1,000 p.p.m.) seed setting increased to 50 per cent but the embryo was slightly smaller than that of the controls. Occasionally these seeds germinated *in situ* (Fig. 2).

In *Aerva tomentosa* it has thus been possible to secure the normal growth of the embryo by culturing unpollinated flowers and spikes at the mature embryo sac stage. When the ovaries alone are cultured, the response is less satisfactory. Further work is in progress to promote the growth of excised ovaries and to rear normal seeds from closed buds.

I am greatly indebted to Prof. P. Maheshwari, under whose guidance this research was carried out. My thanks are also due to Dr. R. C. Sachar for help and interest and to Dr. L. G. Nickell, Chas. Pfizer and Co., New York, for gibberellin.

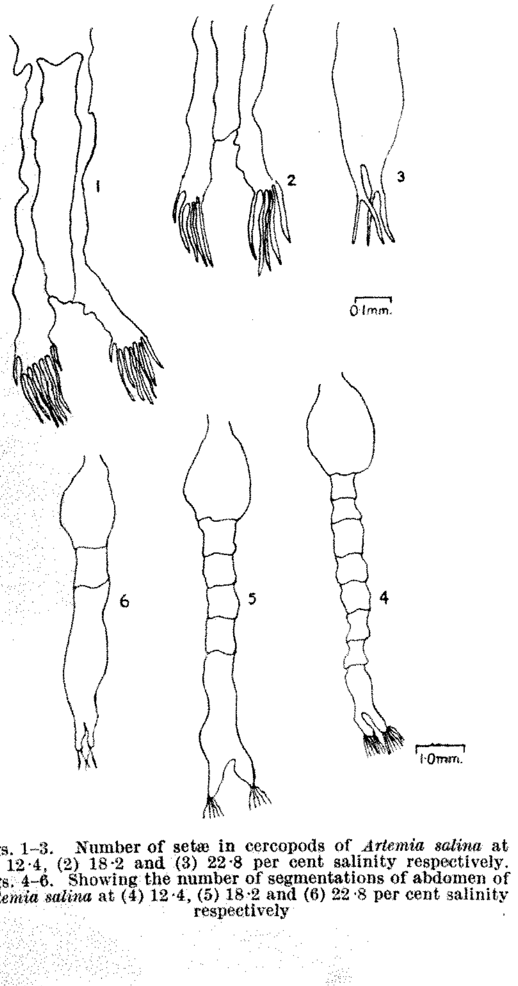
Occurrence of Neoteny in the Genus *Artemia*

THE genus *Artemia* has attracted the interest of many zoologists since the classic observations and experiments of Schmankewitsch[1]. This interest has been renewed by the occasional reconsideration of Schmankewitsch's observations and more rarely by the actual re-examination of *Artemia* species under different salt concentration of the water. Anikin, Samter and Heymons, Artom, Aboyni, and Gajewski have reported[2] morphological variations in response to change in salinity of the medium. But Martin and Wibur and Bond have reported[3] that *Artemias* from the Monterey Bay salterns and the coastal region of central California remain unchanged in different concentration of salt water. The *Artemias* which have shown variations in response to environment have all been Old World in origin, and it appears that no variable *Artemia* occurs in the western United States. The occurrence of *Artemia* from the oriental region was reported by Bond[4] from Tso-kar Lake, Tibet, Kulkarni[5] from Valda pans at Bombay and by Baid[6] from the Sambhar Salt Lake, Rajasthan.

The collection of *Artemia* from the Sambhar lake was brought to the laboratory in April 1957. Some *Artemias* were put in a higher concentration of salt water (18·4 per cent sodium chloride), where they underwent changes in size and in some morphological characters. All of them became small in size and differed considerably from *Artemia salina*. These dwarf *Artemias* were more or less identical with

A. milhauseni. They were actively reproducing in a higher concentration of salt water (22·8 per cent) as well as in lower concentrations (21·4, 16·5 and 8·5 per cent); I watched them for three generations in the laboratory. The experiments were repeated twice, with the same results. It is therefore clear that *A. milhauseni* cannot be reared back into *A. salina* as reported by Schmankewitsch[1]. The probable interpretation of these preliminary results is that *A. salina* of the Sambhar lake is a neotenous form of *A. milhauseni*. To test the variability in this genus and this observation some experiments in the ponds of Jaswant College Botanical Garden, Jodhpur, were carried out.

The pond was filled with lake water. The salinity of the water was diluted by adding distilled water. At 5·6 per cent salinity *Artemia salina* (females) were transferred to the pond. Some of these *Artemias* were also kept in a small pond adjacent to the big pond, the salinity of which was kept more or less constant (5·6 per cent salinity). At intervals of 24 hr., the main pond water and the *Artemias* were studied in the laboratory. Due to the heat, water from the pond had evaporated and consequently the salinity was higher. Some *Artemias* with pond water at 12·4, 18·2 and 22·8 per cent salinity were removed and placed in different aquaria in water of the same salinity as that of the pond water from which they were taken. After saturation was reached, distilled water was added slowly to the pond. The salinity and *Artemias* at different stages were studied in both the ascending and the descending series of experiments.



Figs. 1–3. Number of setæ in cercopods of *Artemia salina* at (1) 12·4, (2) 18·2 and (3) 22·8 per cent salinity respectively. Figs. 4–6. Showing the number of segmentations of abdomen of *Artemia salina* at (4) 12·4, (5) 18·2 and (6) 22·8 per cent salinity respectively

Three well-defined stages during the ascending series of experiments were observed in the change of salinity as well as in the population of *Artemia*. The various measurements of the body as well as salinity are given in Table 1. It was found that *Artemia salina* from water of 5·6 per cent and 12·4 per cent salinity metamorphosed completely into *A. milhauseni* at 22·8 per cent salinity. The changes were observed in the size of the body, segmentation of the abdomen and in cercopods (Figs. 1–6). At 12·4, 18·2 and 22·8 per cent salinity, *Artemia* taken from the pond and transferred to different aquaria having water of the same salinity continued to breed. *Artemia salina* in the small pond (salinity 5·6 per cent approximately) survived without undergoing any structural change. After reaching saturation point (23·2 per cent salinity), the highly concentrated water was diluted with distilled water. *Artemia* individuals were examined at 21·4, 16·5 and 8·5 per cent salinity in that order. It was observed that they were more or less identical with *A. milhauseni* or *Artemia* of 22·8 per cent salinity.

Table 1. MEASUREMENTS OF DIFFERENT PARTS OF THE BODY OF *Artemia salina* IN DIFFERENT CONCENTRATIONS OF SALT WATER

Salinity (per cent)	Median length (mm.)	Abdomen (mm.)	Post abdomen (mm.)	No. of individuals examined	Abdomen median length	No. of segments in the abdomen
12·4	10·3	5·5	4·8	14	0·535	8
18·2	9·1	5·1	4·0	12	0·56	5
22·8	8·0	4·5	3·5	8	0·562	2

No change was observed in the form of *A. salina* up to 12·4 per cent salinity).

From these observations it is concluded that *A. salina* is a neotenous form which is completely metamorphosed into *A. milhauseni* when the concentration of salt in the water is raised to the saturation point. The variations in the genus *Artemia* as reported by earlier workers[1,2] are also explained if we assume that neoteny is common in this genus. The salt lakes of the Old World have different concentrations of sodium chloride, and in consequence *A. salina* differs from lake to lake. The early workers raised each form to the status of a new species; but I believe they are neotenous forms, which differ from each other due to the degree of metamorphosis that each has undergone. They metamorphose completely if the concentration of sodium chloride is raised to the saturation point.

The nature of their environment also suggests that these *Artemias* are neotenous forms. The Sambhar Salt Lake is very salty and only 2 ft. deep; in summer the lake bed is completely dry. Neotony is very common among animals when the environment is hostile; it occurs in populations living in an adverse environment where metamorphosis amounts to death. There is a high mortality-rate in the population of *Artemia* during February and March. They seem particularly weak at this phase of their life-history. Hence if conditions become so unfavourable that all metamorphosed individuals perish, it follows that the population must either become neotenous or die out, since only those individuals which can breed as larvæ have any hope of propagating their kind.

It is significant that *A. salina* which breed as larvæ have an advantage, for they are able to produce offspring sooner than *A. milhauseni*, which may not be able to breed in the unfavourable conditions existing in the Sambhar Lake. Thus *A. salina* of the Sambhar Lake is a neotenous form of *A. milhauseni*, and is well adapted to such hostile conditions.

My thanks are due to Dr. J. P. Harding, British Museum (Natural History), for suggestions, and to Dr. D. K. Mathur for his help and guidance.

AGRICULTURE

Non-Symbiotic Nitrogen Fixation in a Soil of the Nigerian Rain-Forest Zone

COMPARATIVELY little is known of the contribution of non-symbiotic nitrogen fixation to the nitrogen economy of tropical soils. In the tropical rain-forest areas it is generally considered that the soil nitrogen supply, depleted by arable cropping, is built up again during the period of 'bush fallow', presumably by indigenous legumes (and perhaps certain non-legumes) present in the regrowth. That appreciable non-symbiotic nitrogen fixation may occur in the soils of this area was shown in the experiment described here.

A bulk sample was collected from the 0–20 cm. layer of Iwo loamy sand, a latosol developed over gneiss. This soil came from a cropped area on the Faculty of Agriculture Farm, University College, Ibadan. 3-kgm. lots were placed in pots in the greenhouse, and six cultural treatments and two fertilizer treatments applied. Total nitrogen (Kjeldahl plus nitrate) contents are shown in Table 1.

There were appreciable increases in the nitrogen content in the case of the bare soil and the soil to which glucose had been added, as well as a smaller increase in the soil on which *Centrosema* was grown. There was also a small but statistically significant increase in nitrogen when fertilizer containing phosphorus and molybdenum was added.

The increase in nitrogen recorded above for the bare soil is equivalent to approximately 140 lb. of nitrogen or 6 cwt. of ammonium sulphate per acre, an increase of considerable agricultural significance were it to occur in the field. It has been estimated that some 15 lb. of nitrogen per acre per annum are fixed in the soils of the Sudan Gezira, where crops of dura have been produced annually for centuries without the use of fertilizers or manures[1]. Under temperate conditions it has been estimated that legumes may fix 150–300 lb. and free-living nitrogen-fixing micro-organisms 15–30 lb. of nitrogen per acre per annum[2].

The growing of plants on the soil appears to have depressed nitrogen fixation (or to have increased denitrification). The nitrogen contained in the plant material (tops plus roots) amounted to approximately 0·05 gm. per pot for the legume (*Centrosema*) and 0·04 gm. per pot for the grass (*Eleusine*). Thus there was no net increase in nitrogen where the grass was grown, and the increase with the legume was only about half that found in the bare soil.

Since the soils of the rain-forest zone carry growing plants almost continuously (either 'bush fallow' or arable crops) it is unlikely that non-symbiotic nitrogen fixation is important agriculturally, even though the potential capacity for fixation by this means may be great. In most of the indigenous rotations of southern Nigeria the period during which the land is bare does not amount to more than a few months (the time between clearing and planting) in 5–10 years.

The results recorded here are nevertheless considered to be of sufficient interest for the study to be continued and expanded.

Table 1. TOTAL NITROGEN CONTENT OF THE UPPER 20 CM. OF IWO LOAMY SAND AS INFLUENCED BY DIFFERENT CULTURAL AND FERTILIZER TREATMENTS

Fertilizer treatment	Soil kept dry N (gm.)/pot	Soil kept moist for 20 weeks					
		Bare N (gm.)/pot	Bare + 30 gm. glucose per pot N (gm.)/pot	Mulched with wood shavings N (gm.)/pot	*Centrosema pubescens* grown N (gm.)/pot	*Eleusine coracana* grown N (gm.)/pot	Mean* N (gm.)/pot
No fertilizer	1·03	1·11	1·14	1·00	1·04	1·02	1·06
Plus phosphorus plus molybdenum	1·03	1·36	1·23	1·05	1·10	0·90	1·11
Mean†	1·03	1·24	1·18	1·02	1·07	0·96	

* Difference between means for fertilizer treatments is statistically significant ($P < 0·05$).
† Differences among means for cultural treatments are statistically significant ($P < 0·01$). *L.S.D.* = 0·06 gm. nitrogen per pot.

Swellings on the Shoots of Cacao Plants Deficient in Copper

AN experiment to induce symptoms of micro-nutrient-element deficiency on cacao grown in sand-culture was undertaken in 1958. The sand and chemicals were purified as recommended by Hewitt[1] and the water was demineralized by passing it through resin columns. The treatments were done in duplicate; a complete set of treatments was randomized within each of two blocks. Seeds were taken from the centre portions of Amelonado cacao pods (where they are more uniform); they were washed and planted directly into the sand, three seeds to a plastic pot. The plants were watered with demineralized water twice a day for one week, after which 500 ml. of nutrient solution was supplied in the mornings and an equal amount of water in the afternoons. Complete overhead shade was given for one month, after which it was reduced to 50 per cent. Plants were harvested 100 days, 204 days and 321 days after sowing.

Table 1. DIAMETER OF COPPER-DEFICIENT SHOOTS IN THE SWOLLEN AREA OF STEM WHEN THE SWELLINGS WERE FIRST OBSERVED

Distance from tip (cm.)	Treatment without copper		Control	
	Plant *A*	Plant *B*	Plant *A*	Plant *B*
0	4·57	4·30	4·76	4·90
5	4·28	5·25	5·79	6·65
10	5·27	6·90	6·35	6·90
13		8·84*		
15	8·65	8·60	6·84	7·3
15·5	8·82*			
20	10·76	7·65	7·23	7·3
21	10·81*			

* Maximum diameter of swelling.

At 273 days after sowing the remaining plant in each of the two treatments without copper was showing severe leaf symptoms of copper deficiency. Several of the small, immature leaves had abscissed and internodes were short in the area of leaf abscission. Lateral buds were swelling and on plant *A* a strong lateral shoot, 19 cm. long, had arisen below the affected area. These morphological changes indicated a loss of dominance by the shoot tip.

It was at this stage that swellings were noticed on the main shoots of both plants in the treatment without copper, two on plant *A* and one on plant *B*. Measurements of shoot diameter taken on the same day are shown in Table 1. The swollen areas were from 1·5 mm. to 3·5 mm. larger than comparable positions on the control shoot.

During the ensuing 49 days before the plants were harvested there were more leaf flushes, all of which remained on the shoots and showed less evidence of copper deficiency. The shoot tip regained its dominance and no more lateral buds broke. Plant *A* grew 31·1 cm. and plant *B* grew 20·7 cm. during the last 49 days.

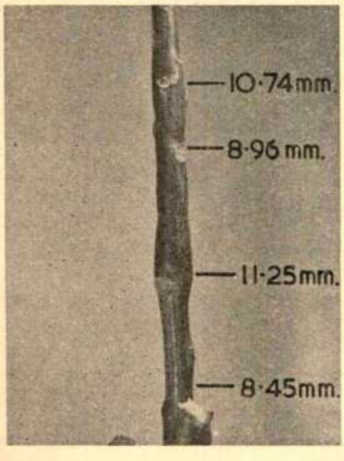

Fig. 1. The swollen area, at harvest, of shoot from plant *A*

Fig. 1 shows the two swellings on plant *A* at time of harvest when the swellings were 1·7 mm. and 2·8 mm. larger than the shoot diameters immediately below the swellings. Transverse sections through the swollen areas showed that the swellings were due primarily to increased xylem thickness.

It has been proved that swollen shoot disease of cacao in West Africa is caused by a virus[2,3]; this does not, however, rule out the possibility of a relationship between swollen shoot disease and copper deficiency.

The complete results of this experiment will be published elsewhere

A Method of increasing the Phosphorus Content of Forages

IN connexion with the feeding of cattle, especially dairy cattle, phosphorus plays a very important part. Forages, the basic need of cattle, should contain as much phosphorus as possible in order to prevent serious pathological troubles.

Phosphate fertilizers are usually applied late in autumn or early in winter. However, it seems that another application of phosphate, in a water-soluble form, late in winter (February or March), considerably increases the phosphorus content of forages. But the efficiency of this second application of fertilizer is improved when nitrogen is associated with water-soluble phosphates (40 kgm./hectare (36 lb./acre) phosphoric acid and 40 kgm./hectare (36 lb./acre) nitrogen).

The results obtained in a series of experiments carried out in 1957 and 1958 on different farms, using several plots of the same paddock in each case, are shown in Table 1.

Table 1

Type of grassland	P and PK in autumn		P and PK in autumn, N late in winter		P and PK in autumn, N + P late in winter*	
	Content of forages		Content of forages		Content of forages	
	P (per cent)	Ca (per cent)	P (per cent)	Ca (per cent)	P (per cent)	Ca (per cent)
Temporary grassland (lucerne–cocksfoot)	0·25	1·01	0·37	1·17	0·39	0·93
Permanent grassland	0·20	1·07	0·22	0·68	0·24	0·67
,, ,,	0·19	0·65	0·21	0·85	0·25	0·89
,, ,,	0·29	0·71	0·24	0·55	0·33	0·70
,, ,,	0·22	1·02	0·24	0·95	0·30	0·95
,, ,,	0·28	0·48	0·32	0·49	0·34	0·57
Average	0·24	0·82	0·27	0·78	0·31	0·79
Ca/P average	3·34		2·89		2·51	

* The fertilizer dressing late in winter involved: 200 kgm./hectare (180 lb./acre), 20 per cent 'nitro-chalk', 200 kgm./hectare (180 lb./acre), 18 per cent superphosphate of lime.

It appears clearly from these figures that applications of nitrogen fertilizer late in winter have a considerable effect in increasing the phosphorus content of plants.

It looks as if a real 'shock' dressing was achieved. The nitrogen–phosphorus association seems to give rise to a synergy, quite favourable to the uptake of phosphorus. This quick absorption by plants reduces fixation of phosphate due to the 'holding power' of the soil. Nitrogen appeared to have an optimum effect when applied in the form of 'nitro-chalk'.

These preliminary results are very encouraging. If they were confirmed, they would help to solve the important problem of ensuring enough phosphate in the cattle ration, especially in that of dairy cows

STATISTICS

A Least-Squares Solution for a Linear Relation between Two Observed Quantities

A linear relation has sometimes to be established between two observed quantities, the precision of each observed value for both quantities being limited and variable from value to value in some known way Examples in astronomy may be found in the treatment of proper motions in moving clusters, in the evaluation of solar motion by proper motions, and in the evaluation of the linear terms of galactic rotation in the solar neighbourhood In such cases the line through the intersection of the two regression lines, with a slope equal to the geometric mean of the slopes of the two regression lines, may often be a good estimate of the best linear relation, but it does not seem to be a least-squares solution in a precise sense Seares[1] discusses at length the best estimates of the regression lines that can be set up, taking into account varying weight for each value and the effect on the regression lines of the distribution of the observed values about the diagram His best linear relation is evaluated as the weighted geometric mean of the two regression lines and he shows[2] that in the case of uniform precision in each quantity his solution reduces to that obtained by Hertzsprung[3] to cover this particular case It would seem, however, that generalization of Hertzsprung's result to cases of varying precision should be possible without bringing in the regression lines at all Jeffreys[4] apparently gives such a solution (his equation 5, § 4 42), but in fact, as was pointed out to me by Dr A J Wesselink, his solution reduces to one of the usual regression lines in the case of uniform precision and not to Hertzsprung's solution Trumpler and Weaver[5] mention several times the importance of 'two-error' least squares solutions in astronomy but nowhere make a solution

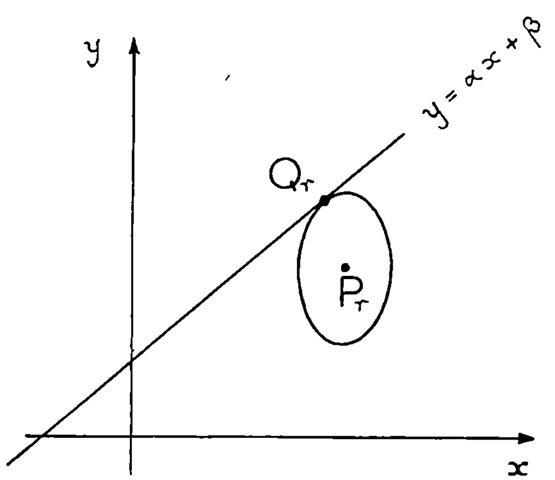

Fig 1

In the present approach we start with a geometric representation, though there are definite similarities to Jeffreys's procedure In Fig 1 P_r is a typical point representing a pair of observed values (x_r, y_r) and the line $y = \alpha x + \beta$ is a possible relation between 'true' values The point Q_r on this line is the point of contact of the tangential ellipse belonging to the set of similar concentric ellipses centred on P_r with equations

$$\frac{(x - x_r)^2}{s_r^2} + \frac{(y - y_r)^2}{t_r^2} = d_r^2 \qquad (1)$$

s_r^2 and t_r^2 are the variances for the precision with which the individual values x_r and y_r, respectively, are known Of all the points on the line $y = \alpha x + \beta$, Q_r, with co-ordinates (ξ_r, η_r), is the one that will give an observed pair of values (x_r, y_r) with maximum likelihood The appropriate value of d_r^2 in (1) for the tangential ellipse is found to be

$$\delta_r^2 = w_r(\alpha x_r - y_r + \beta)^2 \qquad (2)$$

where $w_r = 1/(t_r^2 + \alpha^2 s_r^2)$

This result is similar to that obtained from Jeffreys's expression[4] (§4 42) for the maximum logarithmic likelihood

$$\log L_{\max} = \text{constant} - S \frac{(y_r - \alpha x_r - \beta)^2}{2(t_r^2 + \alpha^2 s_r^2)}$$

that is, $\log(L_{\max}/L_0) \propto \delta_r^2 \qquad (3)$

If uniform prior probability of the α and β is assumed the least-squares condition in obtaining the best values of α and β for a set of observed values (x_r, y_r) is given by the equations ·

$$\frac{\partial}{\partial \alpha}(\prod_r L_{\max}) = 0 \text{ and } \frac{\partial}{\partial \beta}(\prod_r L_{\max}) = 0$$

Transforming to δ_r^2 by (3) we obtain

$$\left.\begin{aligned} \frac{\partial}{\partial \alpha}(\sum_r \delta_r^2) &= \sum_r \frac{\partial}{\partial \alpha}(\delta_r^2) = 0 \\ \text{and } \frac{\partial}{\partial \beta}(\sum_r \delta_r^2) &= \sum_r \frac{\partial}{c\beta}(\delta_r^2) = 0 \end{aligned}\right\} \qquad (4)$$

and the best values of α and β are the solutions of the equations

$$\beta \sum_r w_r = \sum_r y_r w_r - \alpha \sum_r x_r w_r \qquad (5)$$

and

$$\alpha^2 \sum_r w_r^2 s_r^2 x_r (y_r - \beta) + \alpha \left\{ \sum_r w_r^2 t_r^2 x r^2 - \sum_r w_r^2 s_r^2 (y - \beta)^2 \right\} - \sum_r w_r^2 t_r^2 x_r (y_r - \beta) = 0 \qquad (6)$$

The summations in (5) and (6) can only be made numerically if α is known Hence the practical solution is by a method of successive approximation, which will be rapidly convergent if a reasonably good value of α can first be derived graphically or otherwise

If $t_r = k s_r$ = constant, we readily obtain

$$\beta = \bar{y} - \alpha \bar{x}$$

where $(\bar{x}, \bar{y})$ are the arithmetic mean values of the (x_r, y_r) α is then the suitable root of the quadratic equation

$$(\alpha^2 - k^2) \sum_r (x_r - \bar{x})(y_r - \bar{y}) + \alpha \left\{ k^2 \sum_r (x_r - \bar{x})^2 - \sum_r (y_r - \bar{y})^2 \right\} = 0 \qquad (7)$$

This equation corresponds to Hertzsprung's solution, there being in practice no confusion between the two roots, one minimal and the other maximal In such cases the line passes through the 'centre of gravity' of the observed points This is only true for the solution of (5) if we regard the centre of gravity to be that found after applying a weight w_r to each point

Trumpler and Weaver[5] (p 184) say that in two-error solutions the parameter estimates depend upon the 'distribution of', in our notation, the (x_r,y_r) about the diagram In fact, Seares's solution was via regression lines from which the systematic effects associated with the distribution of the (x_r,y_r) had been removed and this is why the distribution entered into the argument Here, we proceed directly from a separate consideration of each point and it is only afterwards that, for example in (7), the marginal variances of the x_r and y_r distributions appear.

Some prior knowledge of the s_r and t_r is, of course, fundamental to a completely meaningful approach to the problem but useful applications of equations (5) and (6) are likely to occur where a problem can be put into the form of solving for the least-squares linear relation only at the expense of introducing widely varying precision for the different observed values of both quantities

HISTORY OF SCIENCE

The Value of π and the Old Testament

Many recent authors of texts containing an account of the historical development of the numerical value of π write under the misapprehension that in the Old Testament its apparent value is 3 Concerning this value, Prof E T Bell writes[1] "This approximation to π is famous for its occurrence in the Old Testament" Quoting 2 Chron 4, 2, Prof L Hogben deduces[2] "The ancient Hebrews were content with taking π as 3" The late Prof G H Hardy could scarcely have examined his two quotations, otherwise he would not have made the blunt observation[3] "It is stated in the Bible that π = 3" P Dubreil quotes[4] 1 Kings 7, 23, and contrasts the approximation with Shanks's value of π to 707 decimal places Quoting 2 Chron 4, 2, Prof T Dantzig comments[5] that this description indicates that the Jews held that π is equal to three Very recently, Archbold quotes[6] Dubreil that the Bible gives the value of π as 3, thereby perpetuating the error in the minds of the next generation of students who read his text These writers therefore fall into two classes, the first regarding π as actually given by 3, and the second regarding the measurements given as only approximate Even some Biblical commentators have fallen into similar error , for example, Curtis and Madsen in their commentary[7] on 2 Chron 4, 2 suggest that the numbers are only approximations

A careful reading of the verses following 1 Kings 7, 23 is sufficient to dispose of this approximation, quite apart from consulting the works of those who have sought to restore the "molten sea" from the Biblical dimensions For it transpires that the circumference of 30 cubits and the diameter of 10 cubits do not refer to the same circle, so it is impossible to conclude that π was taken as 3, either mistakenly or approximately

The diameter of the "molten sea" at its extreme top from brim to brim was 10 cubits But in 1 Kings 7, 24, we must interpret "*under* the brim of it round about there were knops compassing it" The word 'under' may imply that the external surface of the brim need not have been vertical , the cylindrical sides of the "sea" were inclined outwards in order to form the brim, yielding a smaller circle around which the knops (gourds or wild cucumbers) were cast under the slightly larger circle formed by the brim This is confirmed by verse 26, where we read that "the brim was wrought like the brim of a cup, with flowers of lilies", for Sir W Smith's dictionary[8] interprets this as meaning that the brim was curved outwards like a lily or lotus flower, giving at the same time the literal translation of the Hebrew text "its lip was like work such as a cup's lip, a lily flower" The "30 cubits compassing the sea round about" (verse 23) refers then to the general circumference of the "sea" below the brim and not to the special circumference around the brim Thus the circumference of the brim must have been 10π cubits, and the diameter of the cylindrical wall of the "sea" below the brim must have been 30/π = 9 55 cubits , these irrational measurements are omitted from the text

Even the commentators have often missed this point Montgomery and Gehman[9] state that the dimensions are only round figures, thereby failing to see that there is nothing in the text (1 Kings 7, 23–26) that suggests that the figures 10 and 30 refer to the same circle, although their literal translation, "a lily-shaped brim", implies circles of varying diameters

These observations may be verified by noting that Sir W Smith's dictionary[8] gives a general sketch of the "sea" according to the restoration by Keil , a distinct outwardly curving brim exists, with the rows of knops underneath it A larger encyclopædia[10] gives a detailed etching of the restoration according to Calmet, together with a complete axial cross-section of the "sea" , this too shows the characteristic brim, with the rows of knops below it around a circle of smaller diameter than that of the brim

LECTURER IN THE DEPARTMENT OF VETERINARY PHARMACOLOGY—The Secretary, The University, Edinburgh (August 28)

SENIOR LECTURER (with an honours degree in metallurgy and a successful record of research work) IN METALLURGY—The Registrar, Royal Technical College, Salford 5, Lancs (August 29)

TECHNICAL OFFICER (with experience, including administration, in a Physiology or similar Department) IN PHYSIOLOGY at the University of Otago, Dunedin, New Zealand—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W C 1 (New Zealand, August 30)

ASSISTANT LECTURER or LECTURER IN THE DEPARTMENT OF VETERINARY PHARMACOLOGY—The Registrar, The University, Liverpool (August 31)

ASSISTANT LECTURER IN BIOCHEMISTRY—The Dean, Guy's Hospital Medical School, London Bridge, S E 1 (August 31)

LECTURER or ASSISTANT LECTURER (with some industrial and research experience) IN THE DEPARTMENT OF CHEMICAL ENGINEERING to specialize in separation processes, fluid dynamics or thermodynamics and chemical kinetics—The Registrar, The University, Leeds 2 (August 31)

RESEARCH ASSISTANT (with an honours degree in botany, with training in cytology and/or genetics) IN THE DEPARTMENT OF BOTANY, for duties mainly in the University Botanic Gardens, Ness, Cheshire—The Registrar, The University, Liverpool (August 31)

LECTURER IN MECHANICAL ENGINEERING—The Registrar, The University, Nottingham (September 5)

JUNIOR LECTURER IN MATHEMATICS—Prof E C Titchmarsh, Mathematical Institute, Oxford (September 14)

LECTURER (Grade I) IN RADIOLOGY at University College, Ibadan, Nigeria—The Secretary, Senate Committee for Colleges Overseas in Special Relation, University of London, Senate House, London, W C 1 (September 14)

LECTURER (with good qualifications in light current electrical engineering or in physics) IN ELECTRONIC ENGINEERING, and a LECTURER (with a thorough knowledge of the physics of materials, and preferably with research or industrial experience involving solid state physics) IN MATERIALS—The Secretary and Registrar, University College of North Wales, Bangor, North Wales (September 14)

READER (graduate of a British Commonwealth university or equivalent, Corporate Member of the Institution of Electrical Engineers, with teaching and research experience at university level) IN ELECTRICAL ENGINEERING at the University of Hong Kong—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W C 1 (Hong Kong, September 15)

RESEARCH ASSISTANT (preferably with an interest in the ecology and systematics of small mammals) IN THE DEPARTMENT OF ZOOLOGY—The Secretary and Registrar, The University, Southampton (September 15)

SENIOR TUTORS (2) IN PURE MATHEMATICS at the University of Sydney, Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W C 1 (Australia, September 19)

ASSISTANT (with at least an honours degree in biochemistry or equivalent) IN BIOLOGICAL CHEMISTRY—The Secretary, The University, Aberdeen (September 21)

LECTURERS (2) (with experience either in infra-red spectroscopy or in radiochemistry) IN THE DEPARTMENT OF CHEMISTRY—The Deputy Registrar, The University, Edgbaston, Birmingham 15 (September 21)

READER, and a LECTURER IN PURE MATHEMATICS at the University of Western Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W C 1 (Australia, September 25)

CHAIR OF PHARMACEUTICAL CHEMISTRY in the University of Sydney, Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W C 1 (Australia, September 26)

CHAIR OF APPLIED MATHEMATICS in the University of Cape Town—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W C 1 (South Africa, September 30)

LECTURER IN THEORETICAL PHYSICS in the Natural Philosophy Department—The Secretary, The University, Aberdeen (September 30)

LECTURER or an ASSISTANT LECTURER IN THE DEPARTMENT OF PHYSIOLOGICAL CHEMISTRY, for duties chiefly concerned with the teaching of the physiology of domestic animals—The Registrar (Room 29 O R B), The University, Reading (September 30)

LECTURER (with qualifications in any of the branches of zoology, and preferably an interest in insect physiology or some other branch of experimental zoology) IN ZOOLOGY at the University of Tasmania—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W C 1 (Australia, September 30)

READER IN GENETICS in the Department of Zoology at the University of Melbourne, Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W C 1 (Australia, October 1)

AGRICULTURAL CHEMIST (with a good honours degree in agricultural chemistry, and at least two years suitable postgraduate training or experience) in Sierra Leone to advise the Director of Agriculture on specific problems and for investigational studies in the field, including the laying out of field trials and their statistical analysis and interpretation—The Director of Recruitment, Colonial Office, London, S W 1, quoting BCD 63/15/04/T

CHAIR OF PHYSICS in the University of Tasmania—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W C 1 (Australia, October 15)

CHEMIST (post-doctorate), to carry out a programme of exploratory research on a problem in synthetic aromatic chemistry—Dr P Holt, Department of Chemistry, The University, Reading

LECTURER IN INORGANIC CHEMISTRY at the University College of the West Indies—The Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W C 1

PHYSICIST or PHYSICAL CHEMIST (with a good honours degree or equivalent, in physics or physical chemistry, and some years research experience) WITH THE NATURAL RUBBER DEVELOPMENT BOARD, to work in a small team carrying out research on the use of natural rubber in road surfacing materials—The Director of Road Research, Road Research Laboratory, Harmondsworth, West Drayton, Middlesex, quoting "Natural Rubber Development Board"

RESEARCH ASSISTANT IN THE MATHEMATICS DEPARTMENT, to work with Prof H A Jahn and Dr J P Elliott on the theory of nuclear structure—The Registrar, The University, Southampton

EDUCATION IN THE NEW WORLD

THE report prepared by the Science Advisory Committee to the President of the United States is a significant document for all free-speaking peoples (see p. 87 of this issue)*. It presents the views of America's leading men of science and technologists and examines the ways in which American education can be strengthened so that it will more fully meet requirements in this age of science. The principles upon which the report is based and the recommendations stemming from them have immediate relevance to the state of education in Britain to-day.

No one in the United States would deny that the country should have a first-rate system of education. Yet, says the report, many American citizens do not realize that the strength, and even survival, of democratic society are determined primarily by the excellence and appropriateness of its educational patterns. Nor is everyone aware that learning, though beginning during the school years, is a life-long venture; that education is a part of life and not merely a preparation for it. Unfortunately this lack of awareness is as common in Britain as it appears to be in the United States and, even more unfortunately, applies as much to specialists in education as to members of the general public.

A second declaration of the Committee would find ready acceptance in all countries with a democratic system of government. A modern educational system, the Committee believes, should not only sharpen the intellectual capacities and curiosities of each new generation, should not only extract the essential core from ever-accumulating stores of knowledge, should not only find ways to produce new leaders equipped to add to these stores and to create all the new tools that the civilization requires; it must also produce citizens and leaders who will know how to use the knowledge and tools to advance social and cultural life.

Nor should discussions on education, as so frequently happens at educational conferences and meetings, be confined to buildings or budgets or even curricula. These, indeed, are necessary means to the end. We must think of the end itself; to introduce the growing child, the youth, and the adult to the best and most essential elements of the intellectual and cultural experience of previous generations; to do this in such a way that we stimulate curiosity and encourage each individual to look forward, not backward, to develop his own talents to their maximum, and to continue this development throughout his life.

The Committee also proclaims its faith in education as the most important of all social activities. "It is right and it is important that we should expend great effort and resources in order that every American child shall have the opportunity for the ten, the fifteen, or even the twenty years of formal educational experience required to give him full command of his intellectual powers and enable him to live a rich and fruitful life, both as an individual and as a citizen".

These are the fundamentals of education in a democracy and need frequent examination to determine how far practice falls short of precept. In Britain they should form a useful corrective to the ever-present danger of complacency which bedevils educationists at local- and government-level, who, too often, use advances on limited fronts to obscure the lack of progress over the educational field as a whole.

The Committee's statement stands out chiefly for the importance it attaches to intellectual excellence, to the need for stretching students to the utmost of their capabilities, to enhancing the prestige of the teacher and to improving the standards of scientific education both for the specialist and the non-specialist; above all, and as the report makes very clear, for the recognition that the strengthening of science and engineering education requires the strengthening of all education.

The need for much greater emphasis on the gifted—though not at the expense of the less gifted—has considerable significance for Britain to-day. The President's Committee recommends that opportunities should be provided to draw out both gifted and less gifted to the limit of their intellectual and emotional capacities. Unfortunately, education cannot be considered outside the framework of the society for which it is intended and, in Britain, two opposing views have grown up. One, broadly represented as egalitarian, is pursuing policies which tend to reduce the facilities and challenge for more intellectual children by emphasizing that there must be equal opportunities available for all. In their quite natural desire to look after the weaker brethren it frequently means that the less gifted are given relatively greater attention and facilities than those with greater mental endowments. The other view, sometimes described as the superior, seeks, under the guise of character-training, to perpetuate a system in which mere attendance at a well-known school is thought to be more than adequate to make up for deficiencies in intellectual abilities.

The importance of character-training is continually being stressed in the British educational system, and much school work is attuned to this; the achievements are admired by the whole civilized world. Not enough recognition is given to the fact that it is the brain which wins the break-through to new knowledge; the child gifted with high intelligence should always be sought for and given opportunities to expand his intellectual capacities to the utmost. An 'egg-head' deserves wide admiration as a national asset, and should not be treated with mild amusement as a harmless eccentric.

---

* "Education for the Age of Science" (The White House, Washington, D.C., May 1959).

If Britain is to survive in a world where educational systems will become increasingly scientific and technological, much more attention to the gifted child must be given both by those who proclaim equality and by the trainers of character Grammar schools, with their proved records of success, must not be lightly abandoned in favour of experimental comprehensive schools simply to satisfy political aspirations and clamour The major public schools, with their proved records of success, could provide a very much greater service to the nation if entry to them were governed by intellectual and emotional capacity rather than by the parents' ability to pay Unless they are prepared to change in the interests of the whole nation, existing methods of entry to these schools may well lead to their own undoing

Nor can the gifted child be developed where its early days are spent as a member of a class of forty or so children in a primary school Here the aspirations of the Ministry of Education and of the teaching profession are remarkably low in that the provision of classes of thirty at all levels would seem to usher in the millenium The difference between the quality of boarding school education and day school education may not be so much due to the residential factor as is commonly supposed Much more important may be the fact that education in the public schools is organized on a much more individual basis, whereas the State system of education still savours of mass production One of the strengths of the grammar schools has been the individual attention paid to scholars in sixth forms With the development of much bigger sixth forms in comprehensive schools, junior colleges and bigger grammar schools, there is the danger that State schools may decline in quality compared with the public schools, where classes of thirty would often be regarded as three times too many

In his introductory comments to the Committee's report, President Eisenhower writes that one subject warrants special emphasis—"the importance of raising the standing of our teachers in their communities Higher salaries are a first requirement, but we need also to recognize the great importance of what teachers do and to accord them the encouragement, understanding and recognition which will help to make the teaching profession attractive to increasing numbers of first-rate people" The President's belief and wish would find many echoes in Britain as well as a re-echo about whether or not the teaching profession goes the right way to deserve greater prestige The growth of pressure groups inside the profession, the emergence of trade union organization and of threats to strike, and the annual conferences at which the only topics discussed are pay and conditions have all helped to build up a public opinion which does not always see the teacher as a man dedicated to his calling If the teacher is to enjoy greater status he must first of all prove worthy of it This is unlikely to occur so long as the dominant voice comes from teachers who have been trained for only two years and who make up the large majority of the profession

Practical means by which the status and quality of the teaching profession could be improved are described in the report and could well be copied in Britain A closer and continuing link with universities and research institutions, the provision of more refresher courses at which leading men of science and technology keep teachers up to date with new knowledge and discoveries, collaboration between outstanding scientists and teachers in the design of new curricula to give pupils an "introduction to those areas of science and technology essential to an understanding of the problems of a modern society", the scholar's guidance and help in the provision of new text-books of science and technology at all levels, an adequate supply of films, television programmes, slides and tape-recordings to help the teacher in his work—these and other ways should and will increasingly have to be used if the teacher is to remain reasonably up to date in a rapidly changing age of science There is little use in changing curricula unless the teachers have the new knowledge and are competent to teach it

To help the teacher to remain aware of developments in technology, contacts with industry should be much closer than they are to-day This will not only help him to keep abreast of advances in technology, but will also enable him better to understand the industrial life which the majority of his pupils adopt on leaving school

The need to broaden the outlook of the specialist in science by giving him an introduction to other departments of science and technology has been well recognized in Britain by university extra-mural departments The latter have also done valuable pioneering work in enabling the non-specialist to grasp the wider implications of science in society Their efforts have been much curtailed by restrictive financial policies , the reports of extra-mural departments at Oxford, Nottingham and other universities for 1958 should be read in conjunction with the call to action set out in the report of the President's Committee

How much more could have been done has already been shown by those area committees of the British Association for the Advancement of Science which are not only taking outstanding lecturers to large and enthusiastic audiences from women's institutes, etc , but are also answering the long-expressed wish of provincial cities like Liverpool, Nottingham and Sheffield for their own "Royal Institution Christmas lectures" The British Association area committees should now see that any special lectures arranged should not only be available for school-children but also for apprentices, whose formal education is far from complete , receptive and ready-made audiences will also be found in various foremen's and managers' groups inside factories themselves

The Committee's report directs attention to the lack of science teaching in the liberal arts colleges of the United States While in Britain there is no close parallel to these colleges, it is surprising that, even in 1959, the many theological colleges pay little or no attention to the teaching of science It is difficult to believe that some of the time spent on dogma might not more profitably be spent in making prospective parsons familiar with the broad paths of science , courses in social anthropology might be of practical concern to future missionaries

That the strengthening of science and engineering education cannot be undertaken except by strengthening the country's general educational system is a point well made by the Committee and underlined by the President himself In Britain the direction is right, but it may well be considered whether the pace is rapid enough There are still too many black-listed schools Hopelessly overcrowded classes in primary schools present teachers with problems in which education is replaced by mass instruction The high hopes held out for secondary modern schools have not been fulfilled County colleges remain a dream, and, because of the shortage and quality of staff at many technical institutions, the facilities available for many day-release students often account for appalling wastages between the first and last years of City and Guilds and National Certificate courses Shortages of competent lecturers in mathematics and science at teachers' training colleges have led to a vicious circle which results in the bad teaching of mathematics and science in many junior schools The lack of hostels for students in senior technical colleges and universities and consequent living in overcrowded lodgings makes many university lives narrow and drab

These are some of the features of the British educational system which should be examined when too much is made of our advances The report of the President's Advisory Committee should have both a stimulating and salutary effect in Great Britain, in the United States and in the whole Western world

EXTREMELY HIGH TEMPERATURES

Conference on Extremely High Temperatures

Boston, Massachusetts, March 18–19, 1958 Edited by Dr Heinz Fischer and Lawrence C Mansur (Sponsored by Electronics Research Directorate, Air Force Cambridge Research Center) Pp xi + 258 (New York John Wiley and Sons, Inc , London Chapman and Hall, Ltd , 1958) 78*s* net

THIS volume is an account of the first conference on extremely high temperatures sponsored by the U S Air Force Cambridge Research Center, under the chairmanship of Dr Heinz Fischer At first sight it looks as though the U S Air Force were in competition with the Atomic Energy Commission in supporting thermonuclear research at a time when those activities of the Commission called "Project Sherwood" were all classified, and there are clear indications that investigators under the Air Force contract are covering some of the ground the Atomic Energy Commission's scientists had covered long before But the conference was based on a broader realm of science than thermonuclear research , it embraced the study of high-current arcs and materials capable of withstanding extremely high temperatures, with the result that all subjects were treated rather sketchily and a specialist reader is likely to be interested in only one or two papers in the volume

Several papers deal with the development of very high speeds of small pockets of gas driven by shock waves, work not unlike the large quantity of work reported by Post and others from Livermore Janes and Patrick accelerated an annulus of gas between cylinders to 3×10^7 cm /sec with currents rising at 10^6 amp /μsec , and Bostick describes the propulsion of a small volume of plasma at 2×10^7 cm /sec ejected from a deuterium-loaded titanium gun, while Nadig and Bohn give a preliminary account of the shooting of a plasma of exploded wire between long copper plates

Several papers deal with the study of high-powered arcs at atmospheric and higher pressures, arcs dissipating 1,000 kW of d c power, stabilized by a water sheath such as was originally developed at Kiel The plasma of gas emerges from the arc chamber at temperatures up to 15,000 degrees and is constricted to some extent by the electrical pinch-effect Ghai mentions that the most serious limitation to the application of these very high-intensity plasmas has been the erosion of electrodes, and states that in the past year such erosion has been reduced a hundredfold, but unfortunately he does not state how this has been achieved. Bonin and Price, on the other hand, present informative figures on the ablation and erosion of different materials—which might be used in rocket cones—when subjected to the plasmas from these arcs

A session on temperature measurement produced some valuable papers Drummond outlined the microwave properties of high-temperature plasmas and showed that it should be possible to record with microwaves temperatures leading up to fusion Pearce presented valuable calculations about the density of light-emitters deduced from the observed brightness across the diameter of a cylindrical light source, and two papers deal with the deduction of arc temperatures from the hydrogen-line broadening

There are several brief papers on energy storage, capacitative and inductive, and one by Finkelstein outlines the application of a 100,000-joule bank of condensers having specially low inductance (one millimicrohenry total) to develop a betatron field of up to 200,000 gauss over an orbit of 5 cm radius, to achieve the particle acceleration needed to disintegrate matter not into the 'fourth state', namely, electrons and protons, but into the 'fifth state', namely, nucleons and mesons In this connexion Levine *et al* review the problems encountered in generating magnetic fields up to 750,000 gauss for milliseconds The article on the feasibility of thermonuclear propulsion sounds like science fiction and my reaction was "first catch your hare"

T E ALLIBONE

ELECTRON TECHNOLOGY

Electron Physics and Technology

By Dr J Thomson and E B Callick (Physical Science Texts) Pp xiv + 527 (London English Universities Press, Ltd , 1959) 50*s* net

THE publishers say that this work is intended to provide a sound theoretical basis for the student who is pursuing an honours degree in either physics or electrical engineering In fact, the authors seem to have cantered lightly over the fields of electron physics and elementary valve circuits, skirting around difficulties, and reserved their energies for the technology The physicist may be assumed to learn his electron-physics elsewhere, but is it fair to the engineer to show him on p 20 a graph from which the most probable energy of a (conduction) electron in a metal is seen to be about 2eV at room temperature, but then to tell him on p 84 that the most probable electronic energy in a metallic conductor is *kT* ? Again, on p 111 it is stated that a class *B* push-pull amplifier is biased to zero standing current Does not the student deserve a more realistic treatment, even if that requires some further explanation of the actual shape of a valve characteristic ?

Sections 4, 5 and 6, on microwave devices, special-purpose tubes, and materials and construction, are at a much higher standard, and it is perhaps significant that most of the chapters in these parts give some reference to other published work, while the earlier chapters do not The chapter on switching and scaling tubes is particularly valuable

As must always happen in a rapidly developing subject, history has overtaken the authors They have covered travelling-wave tubes up to the stage of using a velocity-jump to reduce beam noise, and they have a chapter on transistors , but they do not deal with the maser, which involves concepts of sufficient importance to be studied by anyone interested in the fundamentals from which the future of electron technology will spring The general impression is that this book is good on electron technology but does not deal with principles as well as one is led to expect from a book which claims to cover physics as well as technology D A Bell

PLANT MORPHOLOGY

Comparative Morphology of Vascular Plants

By Adriance S Foster and Ernest M Gifford, Jr (Series of Books on Biology) Pp xi + 555 (San Francisco W H Freeman and Company , London , Bailey Bros and Swinfen, Ltd , 1959) 9 dollars , 76*s* 6*d*

THE aim of the authors of this very attractively produced text-book is, as stated in the preface, to give not only a purely factual description of the main groups of vascular plants but also to indicate the general principles and objectives of comparative morphology They express the hope that the text will "in some measure orient and vitalize the teaching of plant morphology"

The general plan of the book is a little unusual The first six chapters are described as "orientation chapters" and deal with the principles and problems of comparative morphology Some of the topics briefly discussed are the criteria used in phylogenetic interpretations, the stelar theory, alternation of generations, the telome theory, the phylogeny of sporangia and gametangia, embryogeny A brief account of the aims and methods of experimental morphology is also given Although this arrangement has some advantages, it seems probable that these general discussions would be more useful if they followed, rather than preceded, the descriptive chapters

The main part of the book covers the whole of the so-called Tracheophyta It deals in turn with the Psilopsida, Lycopsida, Sphenopsida and Pteropsida, the last-named being a group which will appear heterogeneous to many botanists The descriptions of the various phyla are excellent, and include some account of fossil representatives and of the cytology As the field covered is so wide, it is, however, inevitable that some aspects should be treated very briefly As might be expected from the research work of the authors, the chapters on the Gymnosperms and Angiosperms are particularly interesting and lucid Many references are made throughout to standard works and other literature, and the references are listed alphabetically at the end of each chapter

The book is fully illustrated by line drawings and photographs For the most part these are excellent and closely related to the text No magnifications are, however, given for any of the figures, and in some instances the specific name of the plant illustrated is omitted from the legend These omissions tend to lessen the value of otherwise excellent illustrations Many of the line drawings are described as being "redrawn" from various sources when it would have been better to use the phrase "based on". This is so in examples where the copying has not been precise (though not misleading), or where shading has been introduced or a pictorial background added In one instance, photographs are said to be "redrawn"

The book may be recommended to students as giving a good general picture of evolutionary trends within the Tracheophyta At the same time it indicates, though perhaps without sufficient emphasis, the difficulty, and often the impossibility, of reaching final conclusions in phyletic morphology The references to recent work on morphogenesis, experimental morphology and cytology should be of value to students as indicating lines of research of great intrinsic interest apart from their possible bearing on the many persisting problems—or "abiding mysteries" as the authors call them—of comparative morphology S Williams

ELECTROPHORESIS IN THEORY AND PRACTICE

The Principles of Electrophoresis

By René Audubert and Serge de Mende Translated by A J Pomerans Pp viii+142+16 plates (London Hutchinson and Co (Publishers), Ltd , 1959) 25*s* net

Electrophoresis

Theory, Methods and Applications Edited by Milan Bier Pp xx+563 (New York Academic Press, Inc , London Academic Books, Ltd , 1959) 15 dollars

IT must be admitted that many people who employ electrophoretic methods have little more than a passing acquaintance with the principles involved in the techniques they are using These two books should enable everyone to know what they are doing, whether they undertake moving-boundary, paper or most other variations of electrophoresis Both these books cover the whole field and so conveniently bring together information which hitherto has been scattered

Audubert and de Mende's volume forms a useful theoretical introduction , the principles of electrophoresis are set out clearly and systematically and the translation has been well done Beginning with the general properties of electrolytes, the book passes on to colloidal systems, electrokinetic potential and electrophoresis Then follow sections on the principles

JOURNAL OF CHILD PSYCHOLOGY AND PSYCHIATRY
and Allied Disciplines

Official organ of the Association of Child Psychology and Psychiatry

Joint Editors

C. B Hindley, *University of London Institutes of Education and Child Health, Child Study Centre*
Elizabeth Irvine, *Tavistock Clinic, London*
Emanuel Miller, *St George's and The Maudsley Hospitals, London*

Pergamon Press have pleasure in announcing a new publication called *Journal of Child Psychology and Psychiatry, and allied disciplines*

The journal will be primarily concerned with child psychology and child psychiatry, but it is recognised that many other disciplines have an important contribution to make in furthering knowledge of the mental life and behaviour of children In the absence of a unified body of generally accepted fact and theory in this field, an important function of the journal will be to bring together contributions of a high quality, springing from different points of view, in order to promote an eventual integration Relevant papers will accordingly be welcomed from such related fields as animal behaviour, anthropology, education, family studies, paediatrics, physiology and sociology

Papers will be of a standard which merits presentation before an international readership They may assume any of the following forms

(a) ORIGINAL ARTICLES—These should make an original contribution to empirical knowledge, to the theoretical understanding of the subject, or to the development of techniques,
(b) REVIEW ARTICLES—These will survey an important area of interest within the general field, and may be offered or commissioned,
(c) Correspondence will not be a feature of the journal, but critiques of papers may be accepted, provided they conform to the scientific level of the journal,
(d) From time to time there may be contributions to symposia on topics of common interest to several disciplines

The journal will appear quarterly, in English The first issue will appear in January 1960

Subscription Rates	To libraries and institutions	**£6 ($17)** per annum
	To individuals who write to the publisher certifying that the journal is for their personal use	**£3 3s ($10)** per annum
	To members of the Association of Child Psychology and Psychiatry	**£3 3s ($10)** per annum inclusive of membership

Pergamon Press books in psychology and allied fields include

MENTAL RETARDATION
Its Care, Treatment and Physiological Base

by **Hans Mautner, M.D.**

A new departure is Dr Mautner's emphasis on the physiological base of the many conditions which lead to mental retardation and especially the relation of brain function to autonomic regulations **35s net ($5 50)**

METABOLISM OF THE NERVOUS SYSTEM
Edited by **Dr. Derek Richter**

Contains the papers presented at the Second International Symposium on Neurochemistry held at Aarhus, Denmark **100s net ($16)**

SCHIZOPHRENIA
Somatic Aspects

Edited by **Dr Derek Richter**

The result of discussions held by a small group of scientists and clinicians arranged with the assistance of the Mental Health Fund and the Ciba Foundation, in London **40s net ($6 50)**

THE SOCIAL PROBLEM OF MENTAL DEFICIENCY
by **N. O'Connor, M.A., Ph.D ,** *and*
J. Tizard, M.A., B.Litt., Ph.D.

"Marks an epoch in the understanding of mental retardation and the training of the backward "—*The Lancet* **30s net ($5)**

BEHAVIOUR THERAPY AND THE NEUROSES
Edited by **Professor H. J. Eysenck**

A series of readings which develop and illustrate a hypothesis to the effect that rational treatments of neurotic disorders can only be developed by drawing upon learning theory, and treating neuroses as learnt habits In preparation

UNDERSTANDING PSYCHOLOGICAL TEST REPORTS
by **Dr T C. Kahn** *and* **Dr. M. B. Giffen,** *U S A F*

A textbook for use in medical schools and by the general non-psychiatric medical practitioner who has occasion to use or refer to psychological reports In preparation

An important work in the field of psychology to be published in November

PSYCHOLOGY, COLLECTA OF SOVIET WORK

Edited by **Dr. N. O'Connor,** *The Maudsley Hospital, London*

Collection of Russian work in psychology from 1917 to date, together with a complete bibliography.

Please write for fully descriptive leaflets

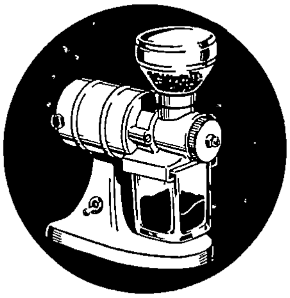
COOKE, TROUGHTON & SIMMS LTD.
YORK, ENGLAND



portable

SAMPLE MILL

£9.18.0

Samples under 100 c.c. of chemicals, drugs, grain, and other dry substances are ground in less than 2 minutes in this portable electric Laboratory Sample Mill.

Particle size is steplessly variable Grinding chamber comes off for easy cleaning Replacement grinding discs can be quickly fitted The entire mill weighs only 5½ lbs and will occupy barely 8″ x 4″ of your bench space Please ask for further particulars

Also available
Micro Mixer/Mills for ultra-fine dry and wet grinding for X-ray diffraction, spectroscopy, electron microscopy, powder metallurgy, etc Stainless steel Micro Hammer Miller for rapid analytical grinding Micro Disintegrator with cooling jacket Other small scale laboratory mills

underlying moving boundary and paper electrophoresis Finally, other zone methods and applications are described Unfortunately, with one exception (and that is a review article), all references are no later than 1954 , consequently some of the matter in the last part of the book is somewhat out of date and some recent important developments are not covered Part of the section on applications is rather sketchily done, and brief descriptions are not supported by references (pp 137–138) The book's chief value lies in its theoretical exposition, but there are one or two flaws The dissociation of proteins (p 13) and of amino-acids (p 70) is represented by concepts which have long ago become obsolete , even more serious is the last paragraph on p 70, which fails to recognize that an ampholyte can have a net charge (and therefore move as a single zone towards an electrode) when it contains both positively and negatively charged groups This is surprising, especially as, two pages further on, the concept of net charge is recognized There are a few less serious errors such as "sulphate" for "sulphide" in Fig 77 and p 106, and in Fig 78 the photometer tracing is reversed relative to the strip Nevertheless, I believe that this book will prove to be of great value to most people who are using electrophoretic methods, and if, as I hope, it reaches a second edition, opportunity should be taken to rectify the few errors and include more up-to-date matter

The book edited by Bier treats in greater detail the theory and practice of electrophoresis It consists of a series of articles on selected topics, each written by experts The first two, by Overbeek and Lijklema and by Linderstrøm-Lang and Nielson, deal very fully with the fundamentals of electric potentials in colloidal systems and acid-base equilibria of proteins There are three excellent chapters on moving boundary electrophoresis (Longsworth on theory and practice , Brown and Timasheff on applications to protein systems) Paper electrophoresis is covered well by Wunderly, and Kunkel and Trautman deal with other zone electrophoretic methods, including important recent developments such as starch gel, cellulose column and immuno-electrophoresis Applications of zone methods are covered by Wieland Bier's article deals with preparative electrophoresis without supporting media and is an excellent survey of methods depending on density gradient, electrodecantation, electrophoresis convection and forced flow electrophoresis An addendum to this section describes electrophoresis in non-aqueous solvents and gives the impression that this is a very recent development, but I think that Karagounis (*Nature*, **161**, 855 , 1948) should receive credit for originating the method described Of particular interest to those working in the medical field is Moore's article on clinical and physiological applications Britten and Lauffer give a fascinating account of electrophoresis of viruses, bacteria and cells, and of the microscopic method of observation

There is a certain amount of overlapping, probably difficult to avoid in a book of this nature, and it might have been a more logical arrangement for Wieland's contribution to have followed that of Kunkel and Tiselius, and for Brown and Timasheff's chapter to have followed Longsworth's But Dr Bier and his collaborators are to be congratulated on an outstanding contribution to the literature of electrophoresis There is little doubt that the hope expressed by him in his preface that this would be an authoritative work has been realized R CONSDEN

A SOURCE BOOK OF FUNGAL PHYSIOLOGY

Physiology of Fungi

By Prof Vincent W Cochrane Pp xiii + 524 (New York John Wiley and Sons, Inc , London Chapman and Hall, Ltd , 1958) 78*s* net

DURING the past thirty years interest in physiology and biochemistry of the fungi has been increasing, but it has received additional encouragement by the publication in the last ten years of several books These have brought a mass of short papers and accounts of experimental work within the easy reach of all biologists Each of these books has treated its subject in a different way, some giving emphasis to chemistry or to functional physiology, others perhaps attempting to review the whole subject at an undergraduate-level The result has been wholly beneficial to mycology itself, for it is now possible for those interested in particular in taxonomy, ecology, pathology or genetics of the fungi to apply to their own work the information gained by laboratory study of physiology Further, the yeasts and a few moulds are no longer the only polite subjects of physiological and biochemical inquiry among the fungi, but have come to be seen for what they often are, rather specialized organisms

Prof Cochrane has had several aims in preparing his book, and these he has achieved with skill He has attempted to review the literature on fungal physiology particularly mentioning work done in the past thirty years, to emphasize those results of a truly experimental and quantitative nature, and to show clearly what parts of the subject present outstanding problems which still require quantitative investigation Certain aspects of physiology have been intentionally omitted, such as the interaction of organisms with one another This subject is so vast that the need for its omission is easily understood

The book as a review of the available information is remarkable for the number of works to which it refers In 379 pages of text some 4 5 × 10^3 references are quoted which are grouped at the end of each chapter so that their use is greatly facilitated Although they are so numerous, they still only comprise a selection made by the author from a much greater number, and this itself indicates the magnitude of the subject of fungal physiology The selection has been good, and as long as one remembers that emphasis has been given to biochemical rather than physiological and to quantitative rather than qualitative information, the book is greatly improved by it Each reference does not, of course, receive detailed appraisal, but the important and difficult aspects of each problem receive comment and criticism designed to place them in proper perspective At times the space allotted to important subjects is a little too restricted For example, the general remarks on metabolism of oligosaccharides in Chapter 5 are unlikely to be easily understood by anyone meeting the subject for the first time

The book as a whole is good and will be found especially valuable as a reference book for all those interested in fungal physiology It may be used to obtain a short critical survey of a problem and also as a guide to references from which fuller details may be obtained

J L HARLEY

A UNIVERSITY OF GRADUATE STUDIES*

By Dr. DETLEV W. BRONK, O.B.E.(Hon.), For.Mem.R.S.

President of the Rockefeller Institute, New York, and of the U.S. National Academy of Sciences

SINCE the beginning of the University of Bologna nine centuries ago, many universities of many kinds have been created in many places; all have been created to satisfy the same deep desire of men to learn and teach. Because universities satisfy that desire, which is unique to human kind, universities have been among the most enduring of human institutions. Their vitality has been attested by their ability to sustain their basic purpose within changing patterns of structure and of action. Various and changing circumstances have evoked universities of various characteristics.

Since the beginning of the Rockefeller Institute, only half a century ago, it has provided rich opportunities for men to learn. It has been a community of scholars who were privileged to explore the frontiers of natural knowledge. Our predecessors have left us a heritage of traditions of intellectual excellence and adventure. They laid strong foundations for a house of learning.

Five years ago we determined to build further on those foundations, so that we might welcome our young successors to this community of scholars and gladly teach and guide them as they prepare for scholarly careers. To-morrow we will speak of new buildings of glass and stone, of modern art and natural beauty. To-day I speak of building an academic structure in which youth may learn from the elder, and the elder have the intellectual stimulus of the younger.

As we have extended the scope of the Rockefeller Institute and assumed the new responsibilities of a School of Graduate Studies, we have thought deeply of our obligations to satisfy the traditional standards of institutions of higher learning. I have personally felt that sense of responsibility keenly, for my life and those of my forebears have been lived in academic places which we prized highly.

I would here quote, as I will do again, from Rashdall of Oxford, the great biographer of European universities in the Middle Ages. "It behooves us not", said he, "to lose or lower the ideal of the university as the place *par excellence* for professed and properly trained students, for the highest intellectual cultivation, for the advancement of science, and not merely for its conservation or diffusion. . . . Whether a particular institution should or should not be called a university may seem by itself to be a little thing, but the name has got to be associated with education of the highest type. It is by no means essential that all should conform exactly to the same pattern. The two most essential functions which a true university has to perform, and which all universities have more or less discharged, amid the widest possible variety of system and method and organization, are to make possible the life of study, whether for a few years or during a whole career, and to bring together during that period face to face, in living intercourse, teacher and teacher, teacher and student, student and student".

Familiar though these functions be, it is appropriate, I think, to state them and restate them in these times of turmoil. The tranquil, contemplative life is harassed and eroded by the busy demands of the moment. The explosive growth of populations requires much wisdom for the preservation of the precious intimacy of relation between a scholar and a scholar and between scholars and those in other walks of life.

Those functions are two of the objectives of the Rockefeller Institute. The first need not be justified to an academic audience such as this, but the significance of that function is less apparent to many all about us who value academic institutions most or only for the training that they gave as preparation for the performance of specific tasks. They value research as discovery of useful knowledge; too few, unfortunately, perceive research as a happy, exciting adventure that gives vitality to our culture.

The Rockefeller Institute is fortunate in its heritage of advice from its founder, who took a longer view and often said to those who studied here, "Don't be in a hurry to produce anything practical. If you don't, the next fellow will. You, here, explore and dream".

It is our purpose to follow that advice and make the Rockefeller Institute a place in which to live a life of study. Though that be a privilege which is sought by many, the Institute will severely limit the number of those who study here, so that those who do so may come together, face to face, in 'living intercourse'. Such limitation is not easy, for refusal never is, and in the United States, all too often, size appeal is an overpowering temptation to sacrifice excellence for numbers. There is appropriate wisdom in the words of Ellery Sedgwick, who said: "One can influence many by inoculating the influential few", as did *The Atlantic Monthly*, of which he was then editor.

Specialization seems necessarily to follow increase of knowledge. New specialties and specialists seem to breed new university departments, and so the scope of universities seems necessarily to grow, and thus to satisfy the needs of a more complex civilization. But some graduate schools could become superlatively good by restricting the scope of their endeavour to immediately related fields.

That was said to me by Abraham Flexner as I began my professorial career in 1926. That year he, also, wrote in *The Atlantic Monthly* some words which I would read as these: "The range of certain universities could be greatly reduced. Moreover, modern science and scholarship being what they are, universities could be very irregular affairs. No single science can be completely represented anywhere; still less, all sciences . . . and institutions most concerned with science would almost inevitably be less adequately developed on the humanistic side Nor does it greatly matter the very incompleteness of single institutions will force all real universities in the higher sense to view themselves as parts of one great organic whole"

---

* Substance of an address delivered on May 21 at the first Rockefeller Institute Convocation for Conferring of Degrees and Dedication of New Buildings (see also *Nature* of June 13, 20, 27 and July 4, 1959).

Perhaps Flexner read Rashdall also, for there I find "The word *universitas* is one to which a false explanation is often assigned for polemical purposes by controversial writers, while the true explanation of it at once supplies us with a clue to the nature and historical origin of the institution itself The notion that a university means a school in which all the faculties or branches of knowledge are represented has indeed long since disappeared from the pages of professed historians, but it is still persistently foisted upon the public by writers with whom history is subordinate to what may be called intellectual edification"

"However imposing and stimulating may be the conception of an institution for the teaching or for the cultivation of universal knowledge, however imperative the necessity of such an institution may seem at times to be, it is one which can gain little support from the facts of history To glance into any collection of medieval documents reveals the fact that the word 'university' means merely a number, a plurality, an aggregate of persons"

One of the most needed functions of a school of graduate study in these days of specialization is to foster broad foundations upon which a man may build competence to deal with problems yet undreamed of Broad foundations of interest in many related fields of science and wide knowledge are essential to a scientist who would be a scholar

Sir George Trevelyan, a Master of Trinity College, Cambridge, in speaking of the friend of whom he then was writing, said "He was an outstanding example of a type that has always specially attracted me the specialist who has a wide outlook, broad knowledge, and warm enthusiasms outside his own subject as well as in it, and more particularly, a man, he was, whose mind has been trained in the splendid discipline of a science, but whose heart and eyes take also delight in the triumphs of art, in the history of man, in the beauties of Nature Such a man is about the best thing that our modern civilization can produce"

We hope that in the Rockefeller Institute we may fit students to become men such as the one of whom Trevelyan spoke We would relate science to all other forms of creative endeavour We will strive to interpret science as a great Odyssey of the human spirit In order to do so we will draw upon all the resources of the learned world that may be available to us in order to emphasize the proper place of science in the total structure of man's creative effort We seek to make an environment in which men and women can pursue knowledge not as a grim undertaking, not as an undertaking for the achievement of immediate, practical, ends, but as a happy, joyous pursuit of knowledge which will enrich all their lives, and the lives of all those about them

EDUCATION FOR THE AGE OF SCIENCE

AN outstanding statement on the place of education in the life of a nation has recently been published by the Science Advisory Committee to the President of the United States of America Issued with the warm encouragement of the President, the report sets out the national goals for strengthening science and engineering education and urges support by all American people to meet these goals (see also p 81 of this issue)

The American outlook is conditioned by the traditional dedication to the proposition that most of her children shall have a long educational experience, that no child shall be deprived of the fullest opportunity to develop his own talents, and that the people of each local community shall, to a large degree, be autonomous in the decisions they make about the education of their own children In theory it is intended that the brilliant child shall be able to develop brilliantly , that the slow or backward child shall be nurtured patiently , that the artisan shall not be considered inferior to the intellectual because he is an artisan, if only he is a good one , that no one shall be condemned to a lowly position or elevated to a high one by the mere circumstance of the wealth, power or prestige of his ancestors

These are the premises, and most American educational policies are based upon them Yet there are inconsistencies Very few Americans, for example, would insist that the words of the Declaration of Independence require that all Americans be equally competent in intellectual matters and that they should, therefore, automatically pass together from grade to grade in school Occasionally this seems to be the policy

Americans do not really think that educated people are dangerous or silly—yet the terms 'egg-head' and 'intellectual' are not always terms of approbation Americans occasionally act as though they feared the word 'excellent', especially as applied to mental achievement In other words, the practices do not always live up to the ideals

After a close and penetrating analysis of the American educational system, the Committee defines certain goals the attainment of which would strengthen science and engineering education in the United States The goals are based upon the belief that a changing civilization will demand an even greater devotion to learning and a greater pride in intellectual achievement "The profound effects of recent advances in science and technology demand that scientific literacy be far more widespread among the American people if we are to solve the problems of this age"

The Committee recommends that

(*a*) Americans should attach greater value to intellectual excellence

(*b*) Every school and college should re-examine its curriculum to make sure that in every aspect it is giving adequate challenge to the intellectual capacities of its students

(*c*) Much more should be done to enhance the prestige of the teacher and to provide him with more effective support in his efforts to improve the effectiveness of his teaching (*d*) Educational programmes should be adapted to the widely varying competence of students, and especially to the needs of the most gifted students

(*e*) Scientific education at all levels should be improved to give better understanding of science to the non-scientist as well as to discover and stimulate more individuals who have the talents to become scientists and engineers

To attain these ends four major areas need specific and urgent attention throughout the educational system These are the curriculum and content of courses, the quality and effectiveness of teachers, the recognition and encouragement of students, and the development of intellectual leadership

The quality and content of the curriculum are central in education At every level in the school, college, and graduate school the curriculum must provide the basic educational materials required of all students, plus the broad selection of opportunities appropriate to the student body involved For those at higher levels in the educational system, it becomes increasingly important that the course content give recognition to the range of abilities of individual students, and, of equal importance, that each student be guided to the subjects best suited to his own innate talents

Especially in rapidly changing fields like science and technology, curricular changes must occur decade by decade, and even year by year At the secondary school level there are problems of balance between vocational and academic courses, and, at the college and university level, the problem of balance between the sciences, the humanities, and the social sciences

The Committee urges scientists and scholars to establish more intimate contact with experienced teachers at all levels, so that the curricula and teaching and learning aids in schools, colleges and universities may take account of the new facts and the new points of view that scientific progress has revealed

The Committee also recommends that a research programme be established by an appropriate foundation or agency in which scientists, scholars and teachers co-operate to design more adequate curricula planned to give all educated citizens an adequate introduction to those areas of science and technology essential to an understanding of the problems of a modern society

Since the content of courses in mathematical and scientific fields at both the secondary and undergraduate college level does not adequately recognize scholarly advances in these fields, the Committee recommends that present efforts be aggressively pursued and substantially expanded in bringing together leading scientists, scholars and teachers in these various subject-matter fields to seek

(1) To bring the course content in each subject at each level into line with the most modern scholarly research in its field, consonant with the level of instruction

(2) To outline, write, publish, and revise the necessary text-books and auxiliary reading materials to achieve these objectives

(3) To develop and supply adequate teaching and learning aids of all appropriate kinds, including motion pictures, television, tape recordings, slides, and other audi-visual materials designed to aid the student in understanding the subject more thoroughly, and especially to relieve the teacher of unnecessary burdens of preparation and instruction, and to enable the outstanding teacher to reach a much larger number of students

(4) To develop and supply laboratory equipment and materials for science courses together with the necessary manuals and reading materials to make the laboratory and field work a far more meaningful, useful and exciting aid to student and teacher

On the quality and effectiveness of teachers, the Committee would like scientists and engineers in universities and industries to establish organized programmes of collaboration with high-school and college teachers in order to reduce the gap in communication and understanding between these groups, rendering assistance and providing teaching material to teachers and their students, and bringing high-school and college students and teachers into more direct contact with scientific and scholarly work in universities and industry The economic and social status of teachers at all levels should be improved, enabling them to devote more of their working time to teaching tasks rather than administrative chores, and allowing them more time for preparation and study in their chosen fields Private and government agencies should evolve State and national programmes for providing substantial rewards, prizes, and other recognition to outstanding teachers in both elementary and secondary schools

A research programme should be sponsored on a national scale to bring together a key group of scientists and scholars to collaborate with teachers and educators on the problem of designing more adequate curricula for the education of high-school and college teachers, especially in the sciences and mathematics, with the aims of reducing the alleged conflict between subject-matter and methodology, making teacher training programmes more attractive to the best students, and bringing about a better understanding between scholars, scientists, teachers, educators and the public in regard to the philosophy, goals, and methods of the educational system

With the assistance and encouragement of the universities, the nation's best scholars should join the nation's great teachers in the task of determining how the great teacher may be brought before an even larger number of students

To recognize and encourage students, the Committee asks the American people to accept as a national goal lifting the student performance to higher levels of excellence by greater motivation and by the provision of rewards for intellectual achievement and more adequate and extensive opportunities and challenges to the highly gifted student A nationwide effort should be made to pay more attention to the academically talented students (that is, those in the upper 15–20 per cent of the age-group in intellectual ability) and to the unusually gifted students (that is, those in the upper 3 per cent of the age-group) Such an effort should involve citizens, school-boards, parents, teachers, together with State and national agencies, public and private Talented students should be recognized at an early age and given guidance and counsel in planning their educational programmes and in preparing for and choosing college and university work These gifted students should be given the necessary help in financing their educational programmes in high school as well as in college and in graduate school Such students should be rewarded and encouraged for their achievement in order that they may take pride in intellectual excellence, even at an early age

In considering the development of intellectual leadership, the Committee concludes that the intellectual, cultural and material advances of any society depend upon the quality of its leadership—upon its scholars, teachers, lawyers, industrial leaders, scientists, engineers, doctors, and other professional people. "These individuals are stimulated and educated in the colleges, universities and graduate schools of the country. To stimulate and educate the intellectual leaders of the future, we maintain a wide variety of colleges and universities located in every region of the United States. These institutions are continually seeking to improve the quality of the intellectual experience which they offer to qualified students in all fields. All, however, need much more help and support in these efforts".

The Committee is concerned about the slow progress which many of these institutions seem to make in their dual task of providing all their students with an adequate introduction to science and technology and the part they play in modern society, and providing adequate educational programmes to those with the talent for and interest in achieving professional careers in science, engineering and technology.

The separate liberal arts college and the college of arts and sciences of the great universities constitute basic training grounds for most of the leaders of to-morrow. There are overwhelming reasons why such citizens should acquire a reasonable introduction to the principles of science and technology on which the modern industrial society is based. Scientists and scholars should give greater attention to assisting the undergraduate colleges in providing adequate programmes in these fields.

From these conclusions it is specifically recommended that the curricular revision programme now being developed for high-school science courses be extended to undergraduate college courses in science and mathematics; aid be rendered to liberal arts colleges in examining their curricula to assure that they are adequately providing for scientific education of the non-scientist as well as of the future scientist or engineer; improving the number and quality of schools of science and engineering should be accepted as a national goal; university graduate schools in science and engineering should be enlarged in number and improved in quality, far greater emphasis being placed upon graduate work in engineering; the engineering colleges of the country should collaborate to improve and modernize their courses in engineering to ensure that able students are attracted to these courses and that they are given adequate training to meet the engineering and technological problems of to-morrow; government agencies concerned with research in science and engineering should re-examine the terms of their research support to educational institutions, with the view of avoiding placing a financial burden or penalty on such institutions by inadequate coverage in research contracts or grants of costs properly chargeable as overhead and for management allowances. Without serving as a subsidy in any way, proper handling of these fiscal matters can make certain that the research support will not affect adversely the opportunity to use the research effectively for the education of students, for the attraction and retention of able faculty members, and for the release of teachers and students from burdensome administrative and fiscal restrictions.

CURRENT TRENDS OF STRONTIUM-90, STRONTIUM-89 AND CÆSIUM-137 LEVELS IN MILK

By W. ANDERSON, L. K. BURTON and J. O. CROOKALL

Physics Department, Institute of Cancer Research: Royal Cancer Hospital, London

IT is widely recognized that milk is an important proximate source of the long-lived fission products present in the human body. In a recent communication[1] we summarized the main information available on the levels of radiostrontium and radiocæsium occurring in milk produced in Great Britain. In the case of strontium-90, the evidence pointed to some regional and seasonal variation, but viewed over the period 1955 until May 1958 it appeared that the levels had remained fairly steady. The picture for cæsium-137 was similar but was complicated by the additional deposition resulting from the Windscale accident. A recent report by Booker[2] extended the available information on cæsium-137 levels, and, in addition, showed that substantial increases of these levels occurred during June 1958 in milk drawn from nine different areas. This article reports detailed experimental observations made by us on the levels of strontium-90, strontium-89, and cæsium-137 occurring in milk produced in west Cardiganshire (Felinfach Creamery) throughout 1958.

The samples referred to in this article form part of the series described previously[1]. It was not possible to obtain dried-milk samples from the Creamery after September 1958 but the series was continued by employing liquid milk samples. To ensure that the sampling procedure remained as fully representative as hitherto, arrangements were made at the Creamery so that the final liquid sample was prepared from numerous periodic samplings of a total day's production. The methods of measurement used were also essentially those described previously. In the case of cæsium-137 in liquid samples, the measurements were conducted on the ash, after a number of tests had shown that no significant loss of this nuclide occurs during either the evaporation or ashing procedures employed.

As before, the samples were received at weekly intervals and measurements made on bulked samples, compounded from four consecutive weekly samples. The values obtained for 1958 are shown in Fig. 1. The main features of the results for each nuclide studied are as follows.

Strontium-90. As shown in Fig. 1*a*, the strontium-90 levels started to rise in April from a steady winter value of about 7·5 s.u., reaching values of 16·5–16·9 s.u. during May–July (1 s.u. = 1 μμc strontium-90/gm calcium). The levels are in the region of 14 s.u. during the autumn but rise again to 16·6 s.u. during November. The levels found for January and February 1959 were 13·4 and 15·3 s.u., respectively. It should be noted that the values found during January–April reflect levels present in winter fodder while later values until December reflect levels occurring in the pastures.

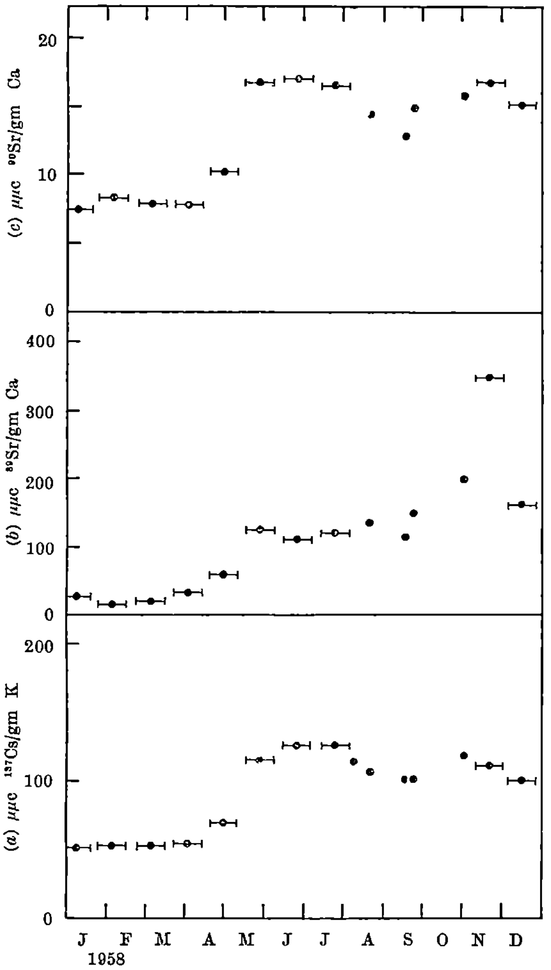

Fig 1 Levels of fission products in milk from Felinfach, west Cardiganshire, Wales (1958)

The values recorded after April 1958 are substantially higher than those found previously by us[1] for milk produced at Felinfach and by Bryant *et al* [3] for milk derived from neighbouring pastures (Carmarthen) Taken together the Felinfach and Carmarthen results gave a picture of fairly steady levels in the range 5 4–8 4 s u over the period October 1956–April 1958, with a temporary rise to values around 10 s u during October–November 1957 A comparison of the mean level, 15 7 s u , for May–August 1958 (Fig 1*a*) with the corresponding level, 7 0 s u at Carmarthen in 1957[3] shows the extent to which the levels of strontium-90 increased in the pastures of this region between 1957 and 1958

Strontium-89 The occurrence of strontium-89 in milk, at levels such as those shown in Fig 1*b*, is a reflexion of recent weapons testing It will be noted that the November level is approximately three times higher than the mean summer level although there is no similar increase in strontium-90 levels This is due to the fact that strontium-89 present in deposited fission products is derived mainly from the tropospheric component of explosion debris, whereas, strontium-90 is mainly deposited from a stratospheric reservoir, depleted in strontium-89 by natural decay[4] The mean November 1958 strontium-89 value (310 $\mu\mu$c /gm calcium) is comparable with that found in October 1957 (280 $\mu\mu$c /gm calcium)[1]

The strontium-89/strontium-90 ratios are listed in Table 1 as average values for each month during October 1957 to February 1959 These values may be compared with the strontium-89/strontium-90 ratios, corrected to mid-month, reported by Stewart *et al* [5] for rain-water collected at Milford Haven, which lies 50 miles south-west from the centre of the Felinfach area This comparison shows that, during pasture feeding periods (Oct –Nov 1957 , May–Aug 1958) the monthly ratios for milk range from 46 to 86 per cent of the corresponding ratios for rain-water, the average value being 70 per cent This is consistent with the results of Bryant *et al* [6], who found strontium-89/strontium-90 ratios in herbage equal on average to 65 per cent of those in rain-water The strontium-89/strontium-90 ratios for radiostrontium in herbage and milk are smaller than the values in rain as a result of the mixing of current fall-out with earlier fall-out, depleted in strontium-89

Cæsium-137 On inspection of Figs 1*a* and *c*, it will be seen that the trend of cæsium-137 levels in these samples follows closely that of strontium-90 The cæsium-137/strontium-90 ratios throughout the year are similar to values obtained for samples produced prior to the Windscale accident This result confirms the suggestion made earlier[1] that cæsium-137, deposited on these pastures from the Windscale pile, is no longer being incorporated in the grass

The maximum error on cæsium-137/strontium-90 ratios, calculated from the values shown in Fig 1, is estimated to be ± 15 per cent The ratios (expressed as $\mu\mu$c cæsium-137/l /$\mu\mu$c strontium-90/l) range, for bulked samples, from 8 7 to 10 5 (mean value = 9 5) Within the limits of experimental error, the ratios may therefore be regarded as constant The weekly variations of cæsium-137 levels during May–August are shown in Fig 2, together with a breakdown of strontium-90 levels for the peak in June It appears from these results that for individual samples the cæsium-137/strontium-90 ratio varies to a small extent, but that in bulked samples, covering a period of a few weeks, the fluctuations tend to average out

As noted recently[7], a practical advantage would be gained if the comparatively straightforward estimation of cæsium-137 in milk could be used to provide an indirect estimate of strontium-90 It appears that, for the present series of samples, this approach would be reliable if supported from time to time by direct strontium-90 estimations It is possible, however, that the indirect estimations of strontium-90 could be misleading for samples derived

Table 1 Strontium-89/Strontium-90 Ratios in Milk (Felinfach)

Month	Strontium-89*/ strontium-90	Month	Strontium-89*/ strontium-90
1957		1958	
October	29 0	July	7 7
November	16 6	August	~ 8 7
December	5 8	September	~ 9 8
1958		October	—
January	3 7	November	18 8
February	2 5	December	11 0
March	3 4	1959	
April	5 8	January	6 7
May	7 2	February	4 9
June	7 2		

* Computed for each month from Figs 1*a* and *b* with due allowance for overlap of values for bulked samples and calendar months

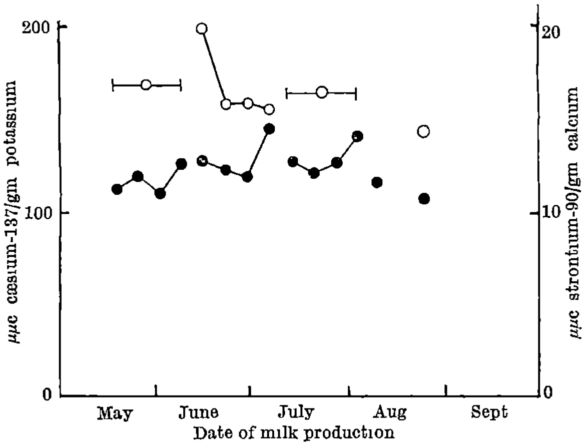

Fig 2 Cæsium-137 and strontium-90 levels in Felinfach milk during May to August 1958 ○, strontium-90 , ●, cæsium-137

from pastures which are more intensively cultivated than those in the Felinfach area[8]

Detailed accounts of the world-wide deposition of long-lived fission products have been published by Stewart *et al* [4,5,9], giving a continuous picture of the accumulation of these radionuclides on the ground In attempting to estimate the future trends of fission product-levels in milk it is important to know how far the levels are determined by the rate of deposition, on one hand, and the cumulative deposition, on the other Previous reports on milk produced in Great Britain suggest that the levels of both strontium-90 and cæsium-137 depend more on the rate of fall-out than on total deposition[1,3,10] The present results throw further light on this complex question

The most recent report by Stewart *et al* [5] shows that the rate of deposition in Great Britain during the summer of 1958 was considerably greater than during previous summers It appears further that this increase was due in substantial measure to the occurrence of unusually high summer rains Using the values reported for specific activity in rain-water at Milford Haven, together with information on the rainfall at six meteorological stations in the Felinfach–Carmarthen area, we estimate that the average total strontium-90 fallout in this region for May–August 1958 was 2 8 times the corresponding value for 1957 A similar estimation shows that the cumulative total rose between June 1957 and June 1958 by a factor of 1 5 The results for strontium-90 in Felinfach–Carmarthen milk provide firm evidence that the average level during May–August 1958 was approximately double the corresponding 1957 level (comparing 15 7 S U , 1958, with 7 0 S U , 1957, gives a factor of 2 2) It will be seen from these figures that the increased levels in milk could be fully accounted for by the increased rate of fall-out, although an appreciable dependence on the cumulative total cannot be excluded Further information on the relative importance of these different factors is given by the strontium-89 results, as discussed below

It is not clearly known what fraction of the strontium-90 present in herbage enters the plant by direct uptake through leaves and stem, as opposed to entry from the soil via the root system[8,10] It appears that a large fraction of the strontium-90 deposited on the ground is retained by many soil types in the top few inches of the soil, but again it is not clear what fraction of the cumulative activity is available to the plant The present results show that the strontium-89/strontium-90 ratios in milk, produced during pasture-feeding periods, are on average at least 70 per cent of the values which would occur in the herbage if there was no contribution from the soil reservoir The ratios in milk during May–August 1958 are approximately five times the corresponding ratios for the cumulative totals of strontium-89 and strontium-90 in the soil[5] A simple calculation based on these results shows that less than 35 per cent (that is, 5 5 S U) of the strontium-90 in the milk produced during May–August 1958 may be derived from the cumulative deposit in the soil The results do not preclude the possibility that all the radiostrontium enters the herbage via the soil but, on that basis, only the deposit of the preceding 4–5 months would be involved It follows from these arguments that the 1958 increase of strontium-90 levels in the Felinfach samples is related mainly to the corresponding increase in fall-out rate Consequently the rise in levels should be regarded in terms of a fluctuation rather than an increase to higher stable levels

The striking parallel in the trends of strontium-90 and cæsium-137 (Fig 1) strongly suggests that rate of fall-out is equally important for both nuclides This result is in keeping with previous indications of the importance of fall-out rate in the case of cæsium-137 levels in milk sampled both in Great Britain[2] and the United States[11] Reports on the trend of strontium-90 levels in milk produced in the United States have tended to link the levels with the cumulative fall-out[12,13,14] It is clear, however, that comparatively large, short-term fluctuations, indicative of a high dependence on fall-out rate, have occurred in these levels[14]

It is not possible to forecast accurately the levels of strontium-90 and cæsium-137 which will occur in milk during the current year, since neither the 1959 rainfall nor the influence of the 1958 series of weapons tests on the specific activity of the rain can be exactly predicted Provided that no further testing occurs, the levels of strontium-89 in milk produced after the summer of 1959 might be expected to be less than one-tenth of the levels occurring during November 1958

We wish to acknowledge our indebtedness to Prof. W V Mayneord, director of the Physics Department, Institute of Cancer Research (Royal Cancer Hospital), for his guidance and encouragement throughout these studies

The studies were supported by grants from the Medical Research Council

OBITUARIES

Mr. R P Howgrave-Graham

By the death on March 25 in his seventy-ninth year of Robert Pickersgill Howgrave-Graham, a remarkable life devoted to such varied subjects as electrical science, horology and archæology was brought to its close

Howgrave-Graham was born in Hampstead into a cultured family His father was the first secretary of the Institute, now the Chartered Institute, of Patent Agents

During 1896–99 Howgrave-Graham studied electrical engineering at Finsbury Technical College under Silvanus Thompson, whom he revered throughout his life as his teacher and his friend Appointed a demonstrator upon the completion of his course, Howgrave-Graham began to assist Silvanus Thompson in his researches, to undertake teaching duties, and to experiment with Herzian waves and high-frequency electric currents He showed himself to be an exceptionally lucid, sympathetic and enthusiastic teacher and an experimentalist of high ability

In the years prior to the First World War, Howgrave-Graham was associated with Lodge and Muirhead in the perfection of the wheel coherer, and he devised during the same period a reed, or fork-maintained, phonic motor of relatively high power During the War, Howgrave-Graham, who was not physically fit for active service, continued his teaching at Finsbury and engaged in various research projects for the Fighting Services The sudden death in 1916 of Silvanus Thompson left him to carry on, practically single-handed, the teaching of physics and electrical engineering at Finsbury

In 1919, Howgrave-Graham left the Finsbury Technical College and took up a similar lectureship at the Northampton Polytechnic, where he continued his teaching work until his retirement in 1945

Within a few months of the end of the First World War, Howgrave-Graham became engaged in the important patent action resulting from the application of Fleming and the Marconi Company for an extension of the term of Fleming's main thermionic diode patent of 1904 He gave evidence in support of the De Forest Company

Although a teacher of distinction and a contributor to the early development of wireless telegraphy, Howgrave-Graham's best-known work is not in the field of electrical engineering but in that of archæology He became an acknowledged expert on medieval machinery and in particular on church clocks His two greatest works in this field were his researches associated with the restoration of the Wells clock, now in the Science Museum, and the Salisbury clock, which was reinstated in the Cathedral in 1956 Howgrave-Graham's patient and accurate historical research on these clocks, which not only contributed notably to their restoration but also incidentally established their dates at 1392 and 1386, respectively, was a work of real scholarship

Photography was, for him, handmaiden to archæology The art of photographing the interesting and beautiful features of the architecture of medieval buildings was one at which he excelled and many of his photographs, some of striking beauty, have been reproduced in books on Gothic art

Happily for him, retirement from teaching presented a unique opportunity to devote himself single-mindedly to his archæology He was appointed as assistant keeper of the muniments at Westminster Abbey There he carried out much skilful restoration work, including the reinstatement and preservation of the earlier funeral effigies which had suffered severe damage by water during an incendiary bomb attack His work on the effigies of Edward III and Henry VII revealed that the features of these effigies were actual death masks

Quiet, kindly and sensitive, Howgrave-Graham was endowed with courage and perseverance and above all with the spirit of inquiry There was, however, something more which made him the delightful and lovable character which he was He enjoyed sharing his discoveries, he had a keen sense of humour and he never took himself too seriously Howgrave-Graham's sense of humour was part and parcel of his feeling for the quaint and the incongruous Perhaps that is why he was so much in tune with the touches of humour of the medieval illuminator or stone mason

Howgrave-Graham married in 1944 Miss Beatrice Purdy, who survives him J Greig

Dr W A Hargreaves

Dr William Arthur Hargreaves died at Adelaide on March 31 in his ninety-third year After an outstanding scholastic career in the University of Melbourne, where he took degrees in arts, science and civil engineering, Hargreaves occupied a number of teaching positions in Victoria and Queensland between 1889 and 1916, when he was appointed director of the Department of Chemistry and Government Analyst for South Australia, a position he occupied until his retirement in 1932

Although Hargreaves was an outstanding analyst and a capable research worker (he was awarded the D Sc of the University of Adelaide in 1916) his greatest contributions to chemistry in Australia arose out of his interest in the teaching of the subject and the part he played in the formation of societies for the promotion of the profession He was a member of the Faculty of Science of the University of Adelaide for thirty-one years and served also on the Australian National Research Council and the Council of the South Australian School of Mines He was an executive officer of the Society of Chemical Industry of South Australia throughout its short life (1915–19) and a foundation member of the Royal Australian Chemical Institute, of which he was president during 1919–21

Outside his profession, Hargreaves's greatest interest was in motoring , he was the first person in Australia to obtain a driving licence and the first to register a motor-car in South Australia, holding the number plate S A 1 from 1906 until 1955 In 1894, he married Camilla Maud Nicholls, of Melbourne, by whom he had a daughter Both his wife and daughter predeceased him Harold J Rodda

NEWS and VIEWS

Psychology at Sheffield

Dr H. Kay

Dr. H. Kay, at present lecturer in experimental psychology at Oxford, has been appointed to the newly established chair of psychology at Sheffield. Dr. Kay read psychology after the English Tripos at Cambridge and for a number of years worked in the Nuffield Unit for research into problems of ageing at the Psychological Laboratory there. During this time, he gained considerable experience of the application of experimental methods to the investigation of manual and other skills. He also took part in field work undertaken by the Unit and was a member of the Naval Medical Expedition to the Arctic in 1949. In 1951, he was appointed to his present Oxford post and played a large part in the development of the Honour School of Psychology, Philosophy and Physiology which was taking place at that time. During the period 1953–56 he led a small team with outstanding success in research sponsored by the Conditional Aid Programme into the fundamentals of industrial skills. He and his colleagues have since extended this work in fruitful directions. Dr. Kay recently spent a year at the National Institutes of Health, Bethesda. During his years at Oxford, Dr. Kay has been active not only in university but also in college teaching, and has latterly been tutor in psychology at Balliol and Merton.

Electrical Engineering in the University of Western Australia :

Prof. A. R. Billings

Dr. A. R. Billings, who has been appointed professor of electrical engineering in the University of Western Australia, graduated from the University of London in 1949, taking his Ph.D. degree in 1957. During 1951–52 he worked as a scientific officer in the Royal Naval Scientific Service before being appointed lecturer in electrical engineering (electronics and communications) in the University of Bristol. His principal interests are in the band-width compression of speech, and in the less usual applications of semiconductors. His earlier work in the first field has resulted in the production of a vocoder which is both simpler and more efficient than the conventional vocoders; while his later work has been concerned with the development of a formant tracker, and a simple synthesizer to go with it. In the semiconductor field Dr. Billings's main interest has been in application of the Hall effect in the new semiconductor compounds. This has resulted in the production of a suppressed-carrier modulator with very low carrier leak, and of a Hall-effect correlator which, when used in conjunction with the early vocoder, has provided new information about the properties of speech.

The chair of electrical engineering in the University of Western Australia is newly established, and Dr. Billings will be the first holder. The research in which he has been engaged is individual work which can be carried on with small-scale apparatus, and he will take with him to Australia some of his equipment from Bristol.

Rockefeller Foundation Grants to C.S.I.R.O. (Australia)

The Australian Commonwealth Scientific and Industrial Research Organization has formed a new Division of Tropical Pastures with headquarters in Brisbane. Dr. J. Griffiths Davies, associate chief of the C.S.I.R.O. Division of Plant Industry and officer-in-charge of the Organization's Plant and Soils Laboratory, Brisbane, has been appointed first chief of the new Division, which will continue to work in association with its parent C.S.I.R.O. Division of Plant Industry. Establishment of the Division of Tropical Pastures reflects the Organization's appreciation of the importance of developing pastures in the summer rainfall areas of Australia, and of the scientific standing of the Brisbane group.

The Rockefeller Foundation has given 30,000 dollars for special equipment for the newly formed Division. The grant will help equip the new Cunningham Laboratory, which is nearing completion. The new laboratory is next to the University of Queensland at St. Lucia, near Brisbane, and will be the headquarters of the C.S.I.R.O. Division of Tropical Pastures. The Division will use its grant to purchase a mass spectrometer and equipment for work with radioactive isotopes. These will be used to expand the Division's work on nitrogen and phosphorus, which are the most important deficiencies in Queensland soils. Dr. J. G. Davies expects that research will make possible a great increase in the carrying capacity of Queensland's pastoral areas.

This is the third large grant that C.S.I.R.O. has received from the Rockefeller Foundation in recent years. Recently the Rockefeller Foundation gave 100,000 dollars for special equipment for the Organization's Divisions of Plant Industry and of Entomology at Canberra. The Foundation also provided 250,000 dollars towards the cost of the giant radio telescope which will soon be constructed at Parkes, New South Wales, for the C.S.I.R.O. Division of Radiophysics.

Radio Telescope for Australia

It has been announced that the contract for the Commonwealth Scientific and Industrial Research Organization's giant radio telescope, which is to be located at Parkes, New South Wales, has been placed with the German firm of Maschinenfabrik Augsburg–Nuernberg A.G. Dr. E. G. Bowen, chief of the Organization's Division of Radiophysics, has played a leading part in completing the design of the radio telescope. It is expected that the total cost of the project will not be far short of £A750,000. Donations towards this have already come from the United States (from the Rockefeller Foundation and the Carnegie Corporation) and from industry and from private donors in Australia. Work to prepare the site is already in hand, and a start will be made to erect the telescope about the middle of 1960. A feature of the telescope will be its radio 'mirror', a saucer-shaped bowl 210 ft. in diameter and covered in wire mesh. This 'mirror' will pick up radio signals from the outermost fringes of the universe It will be slightly smaller than that of the only other giant radio telescope at present in existence (at Jodrell Bank, England) However, the surface accuracy of the Australian radio telescope and the precision with which it can be pointed and driven will all be substantially higher

Proton Linear Accelerator

THE 50 million electron volt proton linear accelerator at the Rutherford High Energy Laboratory, Harwell, came into operation on July 12 This is the first accelerator at the National Institute for Research in Nuclear Science to come into operation It will be used for nuclear research by physicists from universities, the Atomic Energy Authority and a resident team based at the Rutherford Laboratory When in full operation it is expected to have a proton beam intensity many times greater than other accelerators of this kind Because of the high intensity and very well-defined energy it will be possible to do experiments of great value in the study of the interaction between nuclear particles The main parts of the accelerator were designed and constructed for the Atomic Energy Authority by Metropolitan Vickers, Ltd , in collaboration with a team of physicists and engineers from the Atomic Energy Research Establishment who also carried out basic development work on the accelerating structures, and were responsible for the other parts of the machine

High-Pressure Oxygen and Radiotherapy

IT is now well established that when certain cells are deprived of oxygen they become more radio-resistant, and recent work has demonstrated a similar effect upon malignant cells Thomlinson furthermore suggested that in some malignant tumours a proportion of the cells were deficient in oxygen, due essentially to an inadequate local circulation, which could lower their radiosensitivity On this basis, Dr I Churchill-Davidson, Dr C Sanger and Dr R H Thomlinson started in 1954 at the Radiotherapy Department of St Thomas's Hospital a preliminary investigation of the effects of irradiating certain malignant tumours in patients breathing 15–20 times the normal amount of oxygen while in a pressure chamber, which had been designed and presented by Sir Robert H Davis To obtain adequate irradiation at a depth without severe skin damage, γ-rays from a cobalt teletherapy unit were used

Preliminary results in the treatment of advanced carcinomas were encouraging, and in order to try to overcome the limitations of the early prototype apparatus a new unit, specially designed for this purpose, has recently been installed at St Thomas's Hospital Essentially, the unit consists of an aluminium pressure chamber, also presented by Sir Robert Davis, into which are led oxygen pipes and multiple leads which enable the patient to be kept under controlled anæsthesia and observed electronically, although not seen, during treatment A twin-headed cobalt-60 teletherapy unit has also been installed with this chamber, so designed in order to reduce the time of treatment to a minimum

River Purification

THE growth of population and industry has produced problems of river management which had not been foreseen and are not capable of immediate solution Many of the worst cases in Britain are in areas where industry developed and population grew rapidly between 1750 and 1850 , the seriousness of the problem was not appreciated until it had reduced many of the rivers to an appalling condition It was, however, a very long time before it was appreciated that the effects of modern developments in industry and in urbanization on surface waters must be taken into account when plans for the future are being made Even as late as the 1920's the establishment of the beet sugar industry in Britain gave rise to an alarming pollution problem which threatened to turn many of the rivers in our rural areas into a condition as foul and offensive as those in the old industrial areas About the same time, the growth of road transport led to the use of tar as a surfacing material for roads and that gave rise quite unexpectedly to a pollution problem which could have had serious effects on fisheries had it not been tackled in time From then on it began to be realized that the prevention of pollution was, in fact, a practicable proposition and was possible if those concerned, whether industry, local authority or river authority, appreciated the problems and discussed them with other water interests before the waste waters had to be discharged Eventually, this arrangement became an integral part of the Rivers (Prevention of Pollution) Act, 1951, which provides that the consent of a river board is necessary to any new discharge made into non-tidal waters According to F T K Pentelow, of the Fisheries Department, Ministry of Agriculture, Fisheries and Food (*Science Progress*, 47, No 185 , January 1959), that change of policy seems to be having good results, for the very considerable industrial expansion which has occurred since the War has not, so far, given rise to pollution problems on anything like the scale it would have done one hundred years ago

Federation of British Industries

IN the forty-second annual report of the Federation of British Industries for 1958 (pp vi+42 London Federation of British Industries, 1959) it is stated that the gradual discontinuance of research on defence projects sponsored by Government departments has necessitated a fundamental appraisal of the future finance and organization of industrial research Discussions at the National Production Advisory Council on Industry showed that the Government's plans put forward by the office of the Lord President of the Council required a detailed statement of industry's point of view The Federation's Industrial Research Committee has already formulated an interim statement, which was submitted to the Advisory Council in June 1958, and is now undertaking a detailed study of certain aspects of British research practice in relation to methods adopted abroad The report also notes the establishment by the Federation's Education Committee, in co-operation with representatives of the Publishers' Association, Aslib the universities and the technical colleges, of a panel to investigate the alleged shortage of advanced British text-books

Technological Education in Britain

THE tenth annual report of the London and Home Counties Regional Advisory Council for Technological Education (pp 28 London, 1958) covers the year ended August 31, 1958, and refers to a complete reorganization of the Council Under its new constitution, the approval of location of courses under the Ministry of Education's Administrative Memorandum 545 will be carried out by the Distribution of

Courses Committee, and a sub-committee of this committee, which considered the future development of the Council's work, recommended that the help of advisory committees should be sought in considering what advanced educational facilities are required for specific industries and in suggesting future distribution of courses A committee has been formed to consider the relation of the universities with the technical colleges The regional academic board arranged a very successful one-day conference on "Science and the Nation the Role of the Grammar Schools and the Technical Colleges" Of the 141 courses approved to start in 1958–59, 14 were in applied science and mathematics, and 74 in engineering , of the total, 36 were full-time and sandwich courses

Smithsonian Publications

A list of Smithsonian Publications available for distribution on June 30, 1958, has been compiled by Eileen M McCarthy (pp vi+54 Washington, D C Smithsonian Institution, 1958) The papers are distributed gratis, except where price is given, to applicants requiring the papers as an aid to their researches or studies Justification is required if more than one copy each of ten publications is requested, and requests should be addressed to the Publications Distribution Section, Editorial and Publications Division, Smithsonian Institution, quoting the publication numbers in sequence The publications are listed under some sixty-four subject headings, arranged alphabetically

Pharmacy as a Career

The latest booklet in the choice of careers series issued by the Central Youth Employment Executive (H M S O , 9*d*) describes the work of pharmacists in each branch of practice and indicates the qualities needed for the profession , information is also given about the educational qualifications and training required The purpose of the booklet is to help boys and girls to decide whether they are likely to find a satisfactory career in this profession , in most cases the decision as to which branch of practice students should follow is best left until they have gone at least some way with their training and can properly appreciate the relative attractions of the various branches in which they can later specialize

Institute of Physics "Notes for Authors"

The Institute of Physics has recently published a revised edition of its 36-page booklet to assist authors and to serve as a work of reference for all those who wish to contribute to the Institute's publications Under its new title, "Notes for Authors", it gives hints on the preparation of scripts and diagrams, on the layout of mathematics, the correction of proofs, and so on In addition to a bibliography of reference books and works on technical writing, the pamphlet also contains lists of the spellings, symbols and abbreviations used by the Institute Copies of this booklet are obtainable from the Institute of Physics, 47 Belgrave Square, London, S W 1, price 3*s* 6*d*

U S National Academy of Sciences Foreign Associates

The following have been elected foreign associates of the U S National Academy of Sciences Dr V A Ambartsumian, director of the Burakan Observatory in Erevan, Soviet Armenia , Sir Edward Bullard, assistant director of research in the Department of Geodesy and Geophysics, University of Cambridge , Prof Max Hartmann, Max Planck-Institut fur Biologie, Tubingen , Sir William Hodge, Lowndean professor of astronomy and geometry, University of Cambridge

Birbal Sahni Memorial Medal

The Birbal Sahni Medal for 1958 has been awarded to Prof P Maheshwari, professor of botany in the University of Delhi This Medal was instituted by the Indian Botanical Society through a generous grant of 2,500 rupees made by Prof T S Sadasivan of Madras in 1957 to commemorate the memory of the late Prof Birbal Sahni It is awarded every year to a distinguished Indian botanist for his contributions and services to botany in India The first medal (for 1957) was awarded to Prof M O P Iyyengar

United Steel Companies, Ltd Research Department

Dr K J Irvine has been appointed deputy research manager of the United Steel Companies, Ltd He has relinquished his present duties as head of the metallurgy section, which is to be reconstituted Mr J D Murray has been appointed head of a new section to be known as applied metallurgy, which embraces high-temperature metals, alloy development and welding Mr F B Pickering has become head of another new section on physical metallurgy, which deals with the more fundamental aspects of this subject

Announcements

Sir John Russell, formerly director of the Rothamsted Experimental Station, has been elected a member of the Polish Academy of Sciences

Dr D J Price has been appointed visiting professor of the history of science in Yale University for the academic year 1959–60 During the past year Dr Price has been John W Donaldson Fellow and member of the School of Historical Studies at the Institute for Advanced Study, Princeton, New Jersey

Mr Gwilym Hughes has been appointed to succeed Mr Donald Hudson as president of the Pharmaceutical Society of Great Britain , and Mr Tom Reid becomes vice-president in succession to Mr Hughes Mr W Spencer Howells is treasurer for the thirteenth successive year

The Royal Society of Edinburgh, 22 George Street, Edinburgh 2, has arranged to microfilm the thirteen volumes of the David Hume manuscripts Copies of the microfilm will be available by purchase only, and libraries interested are invited to send forward their names, when further particulars will be circulated

The Journées Métallurgiques d'Automne of the Société Française de Métallurgie will be held in Paris during October 19–24 The subject is "Les Gaz dans les Métaux" Further information can be obtained from the Société Française de Métallurgie, 25 Rue de Clichy, Paris 9e

Erratum Dr G Di Sabato writes "In my communication entitled 'Effect of Reduced Diphosphopyridine Nucleotide on the Swelling of Isolated Mitochondria', published in *Nature* for April 4, p 997, column 2, 'sucrose 690 μmoles' in line 6 should be 'sucrose 1,200 μmoles', and '180 μmoles' in line 8 should be '18 μmoles' "

THE GRADUATE SCHOOL IN MATHEMATICAL PHYSICS AT BIRMINGHAM

IN 1956, a Graduate School in Mathematical Physics, leading to a diploma, was instituted in the Department of Mathematical Physics of the University of Birmingham It had been noticed that students who graduated in the honours school of mathematical physics in the Department seemed well equipped, and considerably in demand, for work involving the applications of mathematics to physical problems in industry, government laboratories, etc , because of the training they received in the principles of physics, and particularly in the techniques of translating physical problems into mathematical terms, and of interpreting the solutions from a physical point of view

Entry to the honours course at Birmingham is restricted to students of high ability, who must have the appropriate background in their school training, since the three-year course makes fairly heavy demands on the students It seemed likely therefore that a one-year postgraduate course would be of advantage to students who had taken a degree in mathematics, because they could not—or did not choose to—enter the mathematical physics course, or who graduated from universities at which such a course was not available

The three years of operation of the Graduate School have provided sufficient experience to judge that it can serve the purpose for which it was intended, and that it imparts to the students knowledge and experience which serves them well in their later work The course extends over one academic year (October to July) and is normally intended for honours graduates in mathematics with subsidiary physics In some cases it proved possible to fit in students with somewhat different qualifications Lecture courses attended by the students include a course in methods of mathematical physics (given so far by Dr J G Valatin, who is in general charge of the Graduate School), which forms the central theme of their introduction to the outlook of a mathematical physicist In addition, students normally take selected parts of the lecture courses for honours physicists, and those parts of the final-year course for mathematical physicists (electromagnetic theory, hydrodynamics, quantum mechanics) which they have not previously covered, and which suit their particular needs Other options include mathematical statistics, numerical methods, elasticity theory, statistical mechanics, and usually at least one course in one of the applied science departments All students attend a weekly seminar arranged specially for the Graduate School in which they contribute themselves, and otherwise hear talks by members of the research group in mathematical physics and others It has proved possible to arrange for each individual student a combination of courses which suits his particular interests and knowledge

Although many of these courses are given for other purposes, students find it easy to synthesize their work and to build them into a common foundation of understanding

The number of students in the course has remained small in the first three years, and is likely to continue small until the existence and purpose of the course become more widely known It is therefore premature to give any statistics of the subsequent occupations of students who have obtained the diploma These included work in industry and government laboratories as well as academic research (One student took up postgraduate work in the Mathematical Physics Department at Birmingham, and two joined an applied science department in the University)

The development of the Graduate School was greatly aided by the award of advanced course studentships of the Department of Scientific and Industrial Research, and in some cases by grants from the University of Birmingham

R E PEIERLS

WATER-RESOURCES AND WATER-USE SURVEY

THE study of the use and conservation of water resources is a relatively new geophysical science and one that impinges closely on other sciences such as meteorology and climatology, geology and geomorphology, agriculture, economic geography, demography, etc The importance in the modern world of economic and land-use planning, particularly with reference to so precious a raw material as water, involves the collection of a vast and varied amount of data and information relevant to the assessment of water resources, on not only a national but also an international basis Two papers*, published by the World Meteorological Organization, are useful statements in this important field, particularly in view of the varying scientific standards of recording and observation that are available and possible in different world regions

M A Kohler summarizes briefly the types of hydrological data, the network density of observations required, and network planning, and the techniques for estimating hydrological data that can be used Attention is directed to the impracticability of devising a universally standardized procedure and a scheme is put forward for the creation of a minimum cover of permanent full, partial, and temporary observational stations

The second, longer, technical paper is more closely concerned with techniques for the surveying of surface water resources in a region, and providing estimates of usable water supply. Attention is given to methods which are adapted for use in the absence of adequate hydrological data and to simple techniques of observing hydrological phenomena which may provide useful data with least cost in time and money. Despite the importance of ground-water circulation in all regions—and especially in arid regions—the survey is limited to the discussion of techniques with regard to surface resources. These are a guide to the estimation of requisite rates of replenishment of ground water that are necessary for the effective use of the latter over a period of time. The main topics discussed are the hydrological balance, precipitation, evapotranspiration and its measurement, stream-flow, sediment transport and water supply, and a summary direction for procedure in the matter of water-resource surveys.

---

* World Meteorological Organization Technical Note No 25 Design of Hydrological Networks Prepared by Max A Kohler Technical Note No 26 Techniques for Surveying Surface-Water Resources Prepared by Prof Ray K Linsley Pp v+16+xi+41 (WHI-No 82 TP 32) (Geneva Secretariat of the World Health Organization, 1958) 4 Swiss francs

The special problems and peculiar needs of a densely populated and highly industrialized country such as Great Britain are summarized in an interesting discussion on a water-use survey opened by Prof. W. G. V. Balchin (under the chairmanship of Prof. Dudley Stamp), with contributions from experts representing a very wide range of technical interests in this important field (*Geog. J.*, 124, 476, 1958). Prof. Balchin directs attention to the dramatic increases in water consumption in Britain during the past century, culminating in an increase of 50 per cent in England and Wales and 41 per cent in Scotland during the short period 1938–56. The water storage capacity in the same time has increased by only 46 per cent and 31 per cent, respectively. The area where the consumption is greatest is the area where population is densest and the rainfall least, and where the local resources are already fully employed—that is, in lowland Britain and particularly in the great urban and industrial complexes.

These papers are a salutary reminder, through the many facets to the problem of water conservation that they reveal, of our ultimate dependence on water resources and our need to avoid over-exploitation of a raw material that, in Great Britain at least, people assume all too readily is in abundant supply, and for which in many others the supply is already precarious. ALICE GARNETT

CARNEGIE TRUST FOR THE UNIVERSITIES OF SCOTLAND

THE fifty-seventh annual report of the Executive Committee of the Carnegie Trust for the Universities of Scotland covers the year 1957–58 (pp. iv+74. Edinburgh: Carnegie Trust for the Universities of Scotland, 1959) and includes the financial accounts for the year ended September 30, 1958. A major preoccupation of the Executive Committee during the year was the formulation of a policy to implement its new powers of investment. During the year there were on the books five senior research scholars, thirty-six research scholars in their second or third year, and twenty-five in their first year. For 1958–59 the value of the senior scholarship has been increased to £500 (with an additional £100 for expenses), while scholars at Oxford, Cambridge and London will receive £450; scholars living away from home, attending a Scottish or an English provincial university, £400; and scholars living at home and attending a Scottish university, £350. A grant of £4,000 a year for five years from the end of 1958 was made to the Scottish Dictionaries Joint Council, subject to some conditions with regard to progress. Ten of the research grants awarded during the year were for expenses involved in illustrating the published results of research and five grants were made to authors as a subvention towards the cost of publishing their books.

Four grants are particularly mentioned. The Trust has provided a special heavy-duty vehicle and a 'Folboat' with outboard motor and a grant for running expenses to assist Prof. J. H. Burnett and Dr. D. H. N. Spence, of the University of St. Andrews, in preparing a comprehensive account of the aquatic vegetation of Scotland, a research which involves crossing many moorland roads to examine distant mountain lochs. A grant of £2,500 was made to Prof. R. H. Matthew, of the University of Edinburgh, for a study by a research team correlating the problems of the design of basic dwelling units, lay-out, siting and services with social requirements, with specific reference to contrasting types of social grouping and including a cost study. Another grant was to the University of Glasgow North Rona Expedition, which spent about a month on North Rona and Sula Sgeir, paying particular attention to marine biology. Some very rare species of algae were found and a special census was made of Leech's petrel. A second successful expedition, assisted by a grant from the Trust, was one from the University of Aberdeen, led by Prof. A. C. O'Dell, to St. Ninian's Isle, Shetland, in June–July 1958, in which a most important collection of silver ornaments was uncovered.

Of the ten grants for travel and maintenance made to members of university staffs engaged in research, three were to members of a faculty of medicine, four in science and three in arts. Among these may be mentioned those to Dr. W. I. Card to enable him to visit centres in the United States and Canada, where work of interest and importance in gastroenterology is proceeding; to Mr. Alastair Fraser, to work in Copenhagen in the laboratories of Prof. M. Thomsen and Dr. E. Thomsen, leading authorities on insect endocrinology, and later in Liège, Brussels and Paris; to Dr. C. H. Gimingham to enable him to follow up in Scandinavia his investigations in Scottish heaths, aimed at gaining a comprehensive picture of the ecology of heather, including its reactions to grazing and burning and influences of soil climate and at utilizing this information in an investigation of the ways in which heath lands have originated and are maintained; to Dr. Elizabeth D. Fraser, to enable her to test in America some of her hypotheses regarding perceptual constancy as a function of personality and learning and the effect of metabolic disturbance; and to Dr. P. H. Tuft, to discuss his experimental techniques in embryology in the United States.

THE SCHOOL HEALTH SERVICE IN BRITAIN

THE School Health Service is fifty years old In the half-century of its existence there have been remarkable changes in the health of school children, and in the pattern of illnesses affecting them Both boys and girls to-day are taller and heavier, better clad, better shod and cleaner They reach physical maturity earlier and may expect to live twenty years longer In sharp contrast to the conditions of malnutrition found only too commonly 50 years ago, medical attention is now being drawn towards an increasing number of school children who are too fat

The annual report* of the Chief Medical Officer presents these facts and discloses among other vital statistics that the killing and crippling diseases prevalent at the turn of the century—tuberculosis, rickets and rheumatism—have been practically eliminated The remaining causes of crippling and other forms of handicap are now mainly congenital or hereditary in origin Accidents still kill twice as many children as die from disease, and road accidents are responsible for half the deaths recorded Boys are more liable to death on the road than girls , leaving school in the afternoon is one of the most risky periods of the day

Nearly 250,000 children were found to have verminous heads in 1957 This is about 4 per cent of the total school population "This condition is preventable and there is seldom any excuse for it", says the report "It is essentially a family problem, children being infested and re-infested by adults" The current question of smoking and its relation to lung cancer provides "a striking example of the need for boys and girls, while still at school, to be taught something about healthy living—by example, perhaps, more than by precept In spite of all that has been said and written about the close connexion between the two, many children still smoke cigarettes" A recent inquiry carried out at a mixed secondary modern school in the Isle of Wight disclosed that about a third of the boys and 15 per cent of the girls were regular smokers

The incidence of dental decay has increased in the past few years among school children, and is due "probably to the greater amount of sweets and confectionery eaten since the end of sweet rationing" Fluoridation of water supplies probably offers the best hope of reducing this incidence, "but large scale benefits from this measure can hardly be expected for several years"

One consequence of the changing pattern of ill-health in childhood is that school health service staffs now devote more attention to children who are emotionally disturbed, or who suffer from some handicap which threatens to have a retarding effect on school progress from a psychological cause

There is also the challenge of the delinquent school child which cannot be ignored by the school health service The number of children charged before the juvenile courts has risen from 13,000 in 1913 to 38,000 in 1956 It is right, says the report, that the school health service should concern itself with the problem and co-operate with the other agencies involved In 1957 more than six and a half million children attending about 30,000 maintained and assisted schools were covered by the service More than two million have a periodical inspection during the year

INCENTIVES IN THE BUILDING INDUSTRY

A RECENT Building Research Station report* on incentives in the building industry shows that bonus schemes have an important contribution to make to building efficiency The maximum benefit can only be derived, however, if they are integrated into a rational pattern of management The report enumerates principles on which an incentive scheme should be based as well as the method of operation if it is to be successful

Operation targets, coupled with a recording system giving operation costs, should be used whenever possible The operations should be the visual stages of work, of about one week's duration, and continuous jobs with no hold-ups for other trades

The scheme should be designed to suit individual needs and local conditions This calls for flexibility in targets to suit the local productivity of labour and the distribution of bonus payments The operatives on each site should decide the method of sharing within the bonus group or gang It is necessary to safeguard the quality of work by making site staff independent of production bonus and improving site supervision of quality

A number of conclusions were reached about the methods of operation of an incentive scheme Accurate and well-balanced targets should be maintained by the systematic use of cost information from all the firm's sites and by close consultation with its site staff The incentive effect of a scheme is greatest when it is given a central position in the organization of the firm, especially if administered by the contract management side There should be close liaison between estimating and the fixing of target bonus-rates The principles of the scheme should be kept simple and explained to the operatives so that they can calculate their own bonuses. The bonus units are small gangs

---

* Department of Scientific and Industrial Research Building Research Station National Building Studies Special Report No 28 Incentives in the Building Industry By Alison Entwistle and W J Reiners Pp iv+43 (London H M Stationery Office, 1958) 3*s* net

The bonus paid should be the actual amount of bonus earned; there should be no limit to the amount of bonus that can be earned; the bonus should be paid weekly and as soon as possible after the completion of the operation. The scheme should cover, so far as possible, all the work on the site. Good labour relations on the site are an aid to productivity and should be encouraged by presenting the targets to the operatives for agreement before work starts and a recognized channel for complaint should be established. Provision should be made to allow targets to be modified on a particular site if adequate reason is established. Disputes or complaints should be dealt with speedily and in consultation with the site staff.

SURFACE OF THE OCEAN AS A SOURCE OF AIR-BORNE NITROGENOUS MATERIAL AND OTHER PLANT NUTRIENTS

By Dr. A. T. WILSON

Division of Nuclear Sciences, Department of Scientific and Industrial Research,
Lower Hutt, New Zealand

IN an earlier communication[1] the occurrence of organic nitrogen in New Zealand snows was reported, and it was suggested that this might represent a contribution to the nitrogen economy of New Zealand soils. This article presents further results on the subject and points to the most probable origin of this air-borne nitrogenous material.

Samples of snow have been collected from above the vegetation line to avoid possibility of contamination by plant or animal debris. This was done in preference to the more conventional rain-water sampling which is open to large contamination errors. The analyses[2] of these samples are shown in Table 1.

Since the samples described here were freshly collected snow from regions where no plants or animals exist, contamination from these sources should be negligible. No insoluble inorganic material was visible in the samples, so that cyclic terrestrial dust could not contribute appreciably to the nitrogen found in the samples. This is to some extent further supported by the lack of nitrate in the samples. The samples were collected in early and mid-winter when the pollen contribution would be negligible. It seems that precipitation, at least in New Zealand, does in fact contain appreciable quantities of bound nitrogen which does not arise from contamination.

Origin of Organic Nitrogen in Snow

The problem immediately arises as to the origin of this material. When one considers the geographical position of New Zealand, situated as it is in a westerly air stream and surrounded by thousands of miles of ocean, it is difficult to avoid the conclusion that the source is the ocean itself. The ocean, however, contains only about 0.008 p.p.m. of albuminoid nitrogen. Further, if the snow is analysed in more detail, one sees that it is not merely diluted sea water but that its potassium/sodium ratio is an order of magnitude greater than that of sea water.

In order to explain these facts, it is necessary to postulate that the upper, very thin layer of the ocean has a different composition from that of the rest of the ocean; in particular, that it is enriched in potassium, ammonium, organic material and organic nitrogen, and probably various other materials. It is suggested that most debris (for example, from plankton) is either heavier or lighter than sea water and, if heavier, sinks to form sediments, and if lighter, rises to form this layer, which therefore contains micro-organisms and other plankton in a state of partial decomposition and would be expected to be rich in organic matter. It would also be expected to have an increased potassium/sodium ratio, since many marine organisms concentrate potassium. It is known[3] that when a bubble of gas passes through a liquid-gas interface, the act of the bubble bursting throws up a small droplet from the surface of the liquid into the gas phase. This must occur in the phenomenon known as 'white caps' (that is, when a wave breaks). The haze produced by these particles is quite noticeable on a fine day when a heavy surf is running. Thus, the composition of these droplets reflects that of the surface layer and not that of the bulk ocean.

It is reasonable to assume from the foam produced in rough ocean that some surface-active material is present on the surface of the ocean. During strong onshore winds, large quantities of foam accumulate on the shores of New Zealand which provides an opportunity to sample directly the surface layer of the ocean. A sample of ocean foam was collected on the west coast just north of Wellington. The foam was broken with a silicone anti-foaming agent and allowed to stand. It proved to be 25 per cent solid matter. On microscopic examination, this material was found to be particularly rich in bacteria and also had large quantities of diatoms and fragments of phyto- and zoo-plankton. The chemical analysis of this material is shown in Table 1. It is interesting to note the high nitrogen content and that the potassium/sodium ratio is higher than that in sea water.

The relationship between the surface layer of the ocean and snow water is most clearly seen when one plots the 'excess potassium concentration' against the 'albuminoid nitrogen concentration'. This is done in Fig. 1. The excess potassium concentration is obtained by subtracting from the potassium concentration 1/27 of the sodium concentration, that is, that amount of potassium which would be associated with the sodium in sea water. We see that the results from the ocean foam and the snow water samples lie on a straight line which can be extrapolated back to give the albuminoid nitrogen concentration in sea water. This is strong evidence in favour of their common origin, and supports the hypothesis that the

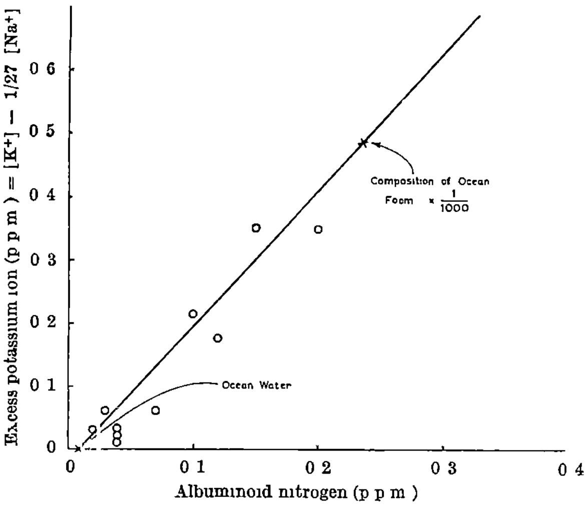

Fig 1

nitrogen in snow originates in the surface layer of the ocean

The above evidence suggests a new path in the nitrogen cycle, at least for New Zealand, and probably for other areas with rough oceans to their windward Elementary nitrogen dissolves in the sea and is fixed by marine micro-organisms These eventually rise to the surface and are caught in the surface layer, where some are partly decomposed by other micro-organisms into ammonia and other products The micro-organisms and their decomposition products are carried into the air by a bursting air bubble in a 'white cap' In the air the droplet would lose its moisture and a part of its ammonia, and as a small and light particle be carried far inland to settle out or to serve the very useful function of seeding rain clouds On reaching the ground this material would contribute to the soil, nitrogen and potassium and possibly other materials necessary for plant growth From the lack of NO_2' and NO_3' in the samples, this path in the nitrogen cycle might be considered more important than the conventional fixation of atmosphere nitrogen by atmospheric electrical discharges, at least for the areas covered by the sampling This then might represent a net transfer of bound nitrogen from the ocean to the land

Table 1

Description of sample	Nitrogen content of snow samples (ref 3)								
	NO_3' (p p m)	NO_2' (p p m)	NH_4^+ (p p m)	Organic (albuminoid) nitrogen (p p m)	Sum (p p m)	Na^+ (p p m)	K^+ (p p m)	Corrected $K^+ = K^+ - 1/27\ Na^+$ (p p m)	K^+/Na^+

Application of Hypothesis to Other Problems

Origin of Ammonia in Air and Rain The presence of ammonia in air and rain has been known for many years Its origin, however, has been in doubt[4] The ocean seemed to be the most likely source except that calculations based on the equilibrium constant between air and water, together with the concentration of ammonia in the sea, rule out this possibility, even though in New Zealand's case there seems to be no other The hypothesis presented in this article would imply that the ammonia is coming, not from the bulk ocean, but from the surface layer and from the evaporation of the small droplets which are thrown up into the air by the bursting bubbles Variable quantities of ammonia will be lost by these droplets to the air, depending on their pH and composition Indeed, the results in Table 1 seem to show that the higher the albuminoid fraction the lower the ammonia retained in the droplet and vice versa This might be due to the buffering effect of the basic nitrogenous material

Potassium/sodium ratio in rain water It is a well-known fact that the potassium/sodium ratio in rain water is often larger by a factor of 10 than that in the sea—the obvious source This can be readily explained in terms of the above hypothesis, since the rain would derive its salts from the surface layer of the ocean, which in turn is rich in marine organisms, many of which are known to have much higher potassium/sodium ratios than the 1/27 of sea water

Charge discrepancy in rain water The total sums of all the charges carried by the anions and cations in rain water sometimes do not balance. This can be explained by the presence of organic compounds balancing the excess charge.

Ocean foam The origin of the foaming agent in the sea is not certain, but it is possible that it is produced by the bacteria themselves and serves to trap their food and also to aid in their aeration

Many of the sheep stations on the New Zealand coasts and islands carry more sheep than might from other considerations be expected, and without aerial top-dressing[5] This effect decreases with distance from the sea, and applies only to areas lying within 10 miles of the coast Could this be the result of wind-blown foam carrying plant nutrients to these coastal areas ?

Bacterial action of the sea There is a discrepancy between the supposed bacterial action in the sea and the very few bacteria found therein[6] Is it possible that a large fraction of these biological processes takes place on the surface layer of the ocean, and that these are not effectively sampled by the normal methods which sample the bulk ocean rather than the surface ?

Life in the inter-tidal zone The occurrence of large quantities of organic matter and nutrients in the surface layer of the sea might provide the food supply for the large amount of life that exists in and near the inter-tidal zone

I wish to thank Mr H J Wood of the Dominion Laboratory, Wellington, for the nitrogen analyses, and Mr A J Heine and Mr G Pallo, Department of Scientific and Industrial Research, for collecting samples

COMBINED EFFECTS OF CORTISONE AND INSULIN ON DEVELOPING CHICKEN EMBRYOS

By Dr PIETRO de FRANCISCIS* and Prof WALTER LANDAUER
University of Connecticut

THE injection of insulin into the yolk sac of chicken eggs after an incubation period of 4–8 days is responsible for the occurrence of a shortening of the long bones of the legs (micromelia) and of abnormalities of the beak , the mean body-weight of such embryos is somewhat reduced The severity of these symptoms varies with the amount of injected insulin[1] The principal effect of cortisone, injected during the same developmental stages, is a marked dwarfing of the embryos, but without the production of skeletal malformations[2] When both insulin and a potent adrenal cortex extract (but of unknown cortisone concentration) were injected after 5 days of incubation, it was found that the incidence of insulin-specific skeletal abnormalities was significantly greater than after the injection of insulin alone[3 4] In similar experiments, but done after 8 days of incubation and using cortisone in combination with insulin, Lunardo and de Bastiani did not find a potentiation of the insulin effect[5] It seemed of interest, therefore, to determine if differences of developmental stage are responsible for dissimilarities in the effects produced by simultaneous treatment with cortisone and insulin or if the discrepancies between our earlier observations and those of Lunardo and de Bastiani have other causes

For our present tests we used eggs of White Leghorn fowls Sterile solutions of cortisone (cortone acetate, Merck) and of insulin (Lilly) were injected into the yolk sac after 4 or 8 days incubation. The details of our experiments are presented in Tables 1 and 2 In recording skeletal abnormalities, all degrees of shortening of the legs were pooled , similarly, all types of beak defects were grouped together The incidence of other skeletal abnormalities was very small and was not separately recorded , these defects occurred with about equal frequency in all groups and, since there was no reason for believing that they owed their origin to our experimental procedures, they were added to the 'normal' groups

Untreated eggs served as controls of the various experimental groups For the test reported in Table 1 we had 37 fertile and untreated eggs , 33 of these

---

* Fellow of the Italian National Research Council

Table 1. EXPERIMENTS IN WHICH CORTISONE, INSULIN, OR BOTH CORTISONE AND INSULIN WERE INJECTED INTO THE YOLK SAC OF WHITE LEGHORN EGGS AFTER 96 HR. OF INCUBATION AND AT THE DOSAGES GIVEN BELOW

	Cortisone			Insulin			Insulin and cortisone		
Experiment	1	2	3	1	2	3	1	2	3
Insulin units/egg	—	—	—	3.2	3.2	4	3.2	3.2	4
Cortisone, mgm./egg	1.25	1.25	1	—	—	—	1.25	1.25	1
Number treated	26	27	30	26	27	30	54	48	90
Survival to eighteenth day, per cent	57.7	81.5	76.6	84.6	63.0	73.0	37.1	47.8	35.5
Number survivors	16	22	23	22	17	22	20	23	32
Body-weight, gm.	14.26 ± 0.98	13.73 ± 0.86	13.90 ± 0.83	19.59 ± 0.81	15.15 ± 0.79	13.37 ± 0.73	12.70 ± 0.87	8.71 ± 0.50	10.14 ± 0.67

Body-weight, gm.	11.87 ± 0.52	13.92 ± 0.65	16.56 ± 0.45	18.20 ± 0.47	16.95 ± 0.50	17.75 ± 0.49	13.53 ± 0.42	13.24 ± 0.42	14.85 ± 0.56
Normal, per cent	100	100	100	50.0	27.8	34.1	81.3	71.4	49.2
Short legs, per cent	0	0	0	50.0	72.2	65.9	17.9	28.6	50.8
Abnormal beak, per cent	0	0	0	0	5.6	0	5.1	0	18.6

In those groups in which both hormones were injected the ratio of cortisone to insulin amounted to 0.47 in experiments 1 and 2, and to 0.25 in experiment 3. All living embryos were weighed and examined after 18 days of incubation. Incidence of 'normal' embryos and of abnormalities of the legs or beak in percentage of survivors to eighteenth day. Standard errors of body-weight.

(89.2 per cent) survived to 18 days and the embryos at that age had a mean body-weight of 20.95 ± 0.53 gm. As controls for the experiments of Table 2 we had 26 fertile and untreated eggs; 22 of the embryos (84.6 per cent) lived at 18 days and had a mean weight of 19.37 ± 0.56 gm. None of these 55 embryos showed skeletal malformations of the kind with which the present discussion is concerned.

Effects on survival. Among embryos treated at 4 days with both insulin and cortisone the mortality was consistently higher than it was in the groups treated with either hormone alone. In fact the toxicities of insulin and cortisone were nearly additive, and most of the group differences in mortality (or survival) are highly significant. At 8 days, on the other hand, survival after the combined treatment did not differ significantly from that occurring after injection of either insulin or cortisone. Comparing the experiments at 4 and 8 days, and taking into account such dissimilarities of dosage as existed, no consistent or significant changes appear to have occurred in the toxicity of either cortisone or insulin. Highly significant differences are found, however, between the combined treatments at the two developmental stages. In experiments 1 and 2, in which the ratio of cortisone to insulin was higher at 8 days than at 4 days (0.47 vs. 0.39), the differences amounted to 31.4 ± 8.65 and 39.7 ± 8.90 per cent respectively; in the two third groups, with identical ratios (0.25), the difference in survival was 38.2 ± 7.04 per cent.

Effects on body-weight. Following treatment after 4 days of incubation, the injection of both hormones led in all three groups to a greater retardation of growth than that produced by either insulin or cortisone. In groups 2 and 3, the mean body-weights, after combined treatment, fell significantly below those of the groups treated with either cortisone or insulin alone. At 8 days the combined treatment led to a significantly lower body-weight in comparison with the insulin-treated embryos; but the differences between the groups that had been injected with both hormones and those that had received only injections of cortisone were neither consistent nor statistically significant. A comparison of the treatments at the two development stages reveals some interesting differences. Against the lowest amount of cortisone which we used (1 mgm./egg) the 8-day embryos had become significantly more resistant than those treated at 4 days, their mean body-weight being 2.66 ± 0.94 gm. higher; the results of experiments 1 and 2 are not directly comparable because of dosage differences. The injection of 3.2 units of insulin at 4 and 8 days did not produce significant dissimilarities in body-weight, but after 4 units the 8-day embryos were less retarded (difference: 4.38 ± 0.88 gm.). The results for combined injection of insulin and cortisone in experiments 1 and 2, because of dosage differences, do not allow a comparison between 4 and 8 days, but the results of tests with 1 mgm. cortisone and 4 units insulin (experiments 3) demonstrate that growth of the embryos treated at 8 days was much less retarded than it was following injection at 4 days (difference: 4.71 ± 0.27 gm.).

Teratogenic effects. As one would expect, the incidence of malformations increased with dosage in the groups treated with insulin alone and in those treated with insulin and cortisone. This was true at both developmental stages. A comparison of the effects of insulin treatment with the results of the combined injection of insulin and cortisone shows no significant differences in the incidence of skeletal defects at the 4-day stage, except for a slight but consistent trend of the abnormalities to be more extreme in the groups treated with both hormones; in the groups tested at 8 days, on the other hand, the combined treatment was less teratogenic than injection of insulin alone. For the pooled data of experiments 1 and 2 (with identical ratios of cortisone

Elements of Solid State Theory

G. H. WANNIER

A clear and logical introduction to the basic concepts of solid state physics for post-graduate and final year undergraduate students It can be used both as a class text and for private study. Each chapter includes a short bibliography and a number of problems.

DIGITAL DATA PROCESSING

The SHAPE Air Defense Technical Center has a few vacancies in the field of high-speed digital data-processing

Applications are invited from suitably qualified persons with interest in one or more of the following fields

Digital computation.
High-speed analog-digital conversion.
Computer input and output devices.
Transistor and magnetic-core techniques, applied to computers.
Cathode-ray tube displays.

The basic salaries will be based on the European average for corresponding background and experience Successful applicants from foreign countries will benefit by a number of privileges, including a foreign allowance of the order of 70% of the basic salary, and reimbursement of the cost of moving their families and household effects to The Hague and back to their country of origin on termination of contract The total income is tax free in the Netherlands

Applications, containing detailed information on training and past experience, should be sent as soon as possible to

The Director, SADTC, P O Box 174, The Hague, Netherlands.

An Introduction to Mathematics for Students of Economics

J PARRY LEWIS

For economics students whose mathematics were abandoned at an early age, this book revises elementary algebra and introduces the necessary trigonometry and co-ordinate geometry before proceeding to a longer treatment of calculus The author guides the reader through the processes of differentiation and integration exponentials, and problems of maxima and minima of functions of one independent variable, before introducing functions of many variables and such topics as Lagrange multipliers *With diagrams 40s*

Nuclear Reactor Physics

RAYMOND L MURRAY

A logical and straightforward introduction to the methods of analysis of reactor design with many numerical examples drawn from practical situations in the reactor field The main emphasis throughout the text is on the distribution in energy and space of neutron flux, the determination of the critical amount of fissionable material, and the transient behaviour and control of the reactor as a source of heat *Diagrams 30s*

MACMILLAN BOOKS

Transistor Electronics

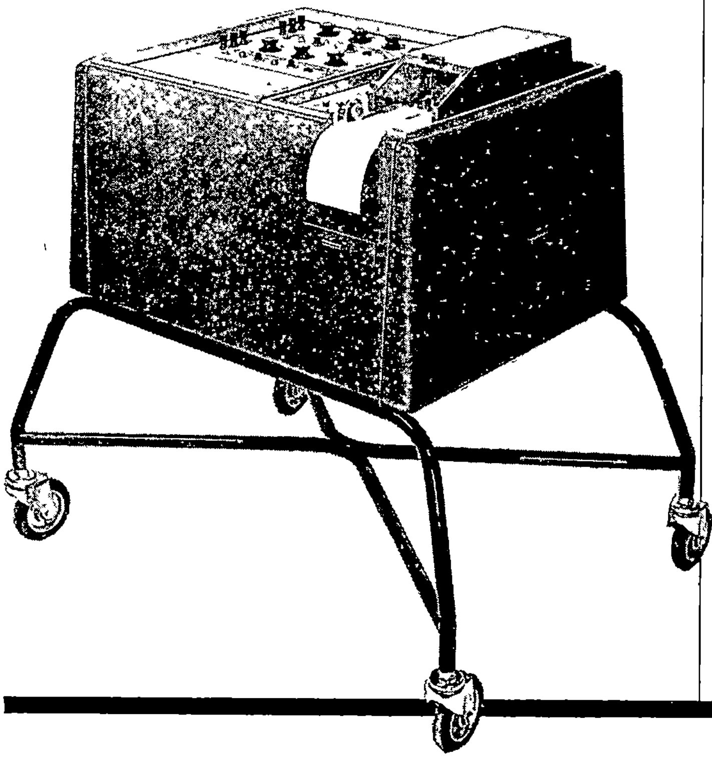
Immediate & permanent CHART RECORDINGS

minirack

MOBILE PEN EQUIPMENT
INSTRUMENT TYPE MPE 223



The advantage of seeing a chart recording immediately cannot be overemphasized

Most recording work is done to compare in detail the relationship and sequence of waveforms produced by electrical and physical phenomena, and if the records are seen while these actions take place, a much more intimate grasp of the relationship is obtained

The Minirack MPE 223 is designed for constant use at high capacity It is extremely sensitive and robust, and the recording element is a simple pen unit that is foolproof.

The advantages of this machine will be obvious to all research workers

QUANTITY PRODUCTION ENABLES THIS INSTRUMENT TO BE SOLD AT THE LOW PRICE OF £388.

The Minirack MPE 223 two channel pen recorder

STANDARD M940B PEN UNIT:

LENGTH OF PEN ARM 10 cm

MAXIMUM DEFLECTION 4 cm peak-to-peak

FREQUENCY RESPONSE Flat to within ±10% D C to 55 cps

SENSITIVITY 1 mm per milliamp approx

LINEARITY Better than 2% of full scale deflection

Special pen units can be made to customers' requirements having
(1) Lower impedance coils
(2) High sensitivity at the expense of frequency response

MR512 AMPLIFIER:

Each pen unit is driven by a MR512 amplifier to the following specification

INPUT IMPEDANCE 1 2 Megohms

OUTPUT IMPEDANCE 250 ohms

MAXIMUM LINEAR OUTPUT CURRENT SWING ±30 mA

Linearity in this range better than ±2% of maximum output current

MAXIMUM SENSITIVITY 240 milliamps per volt

FREQUENCY RESPONSE Flat from D C to 1 Kcps 30% down at 5 Kcps

OUTPUT LIMIT RANGE Approximately 85 to 140 volts output across a 4000 ohms load

watch this space

this is where you will be fitting your latest item of laboratory electrical equipment; whatever goes here must be above suspicion. So when you come to fill this space, think in terms of Siemens Ediswan . . .

We use—and misuse—all kinds of our own equipment in our own laboratories. So when we design and manufacture for *you*, we incorporate ideas and improvements that are fed back from a resident panel of keen critics whose only interest lies in getting the best equipment possible for the job in front of them. Here are a few of the items in which you reap the benefit of their influence and experience.

Stabilised Power Units

These units are manufactured to tight specifications and offer an extensive range of stabilised outputs. They incorporate a number of additional facilities and are all designed for standard 19-in. racking or bench use. We'll be happy to send you our latest catalogue describing this equipment and giving all the essential facts about it for ordering. Make a note of these associated Siemens Ediswan products; we invite you to send for literature or fuller information about those that interest you.

Siemens Ediswan
Clix Radio and TV Components—
Valve Holders, Plugs, Sockets, Screening Cans, etc:

Siemens Ediswan
PTFE Insulated Instrument Wire—
In 11 colours (and with trace). Conforms to Sections B & G of Specification EL. 1930 Ministry of Supply (Air).

Stabilised Power Unit Type R.1095

Outputs:	(1) Continuously variable highly stabilised D.C. output between 120 and 250 volts. Load 0-50 mA. (2) Unstabilised centre tapped 6.3 volts A.C. supply at 3 amps.
Stability:	10 volts mains change or 0-50 mA load change result in less than 0.15V change of output which is effectively independent of mains frequency and waveform.
Output Resistance:	Less than 3Ω under all conditions.
Ripple:	Approximately 2mV R.M.S. with either positive or negative terminal earth.

Low Frequency Oscillator Type R.2125

For testing, calibrating and setting up amplifiers, vibration recorders, wave analysers and oscilloscopes.

Frequency Range:	1 c/s—130 Kc/s.
Frequency Accuracy:	2%
Output:	Sinusoidal. Balanced push-pull, 50 volts p-p. maximum on open circuit.
Attenuator:	5 x 20dB steps plus 0-20dB continuously variable.
Output impedance:	600Ω-0-600Ω.

Bench or 19-in. rack mounting.

High Voltage Capacitors

Behind every TMC Capacitor are the skills and resources of an organisation justly proud of its close association with leading groups in every branch of electrical engineering. It is one of the results of this collaboration that we see the widespread use of TMC High Voltage Capacitors on pulse-forming networks and delay lines for radar where their special features of LOW INDUCTANCE and MINIMUM DIMENSIONS are particularly valuable.

Other applications:

* H.V. SMOOTHING CIRCUITS

* X-RAY APPARATUS

* IMPULSE GENERATORS

* ENERGY STORAGE

We shall welcome your enquiries whatever your requirements are in the H.V. field: a.c. d.c.: or pulse applications.

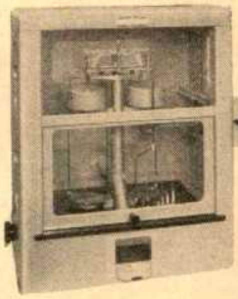
STANTON PRECISION BALANCES

Trade Mark

STANTON INSTRUMENTS LTD.,
119, Oxford Street, London, W.1. Telephone:
Gerrard 7533/4

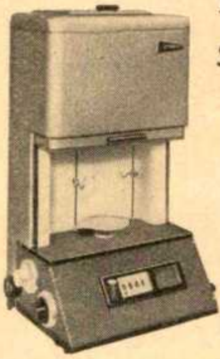
New Feature – **Set of weights included**



STANTON A.49

Already one of the most popular balances in our range. A set of five weights from 10–100 g is now built into the case on a small turntable adjacent to the pan, for greater convenience and quicker weighing.
Capacity 200 g. Sensitivity 0.1 mg.

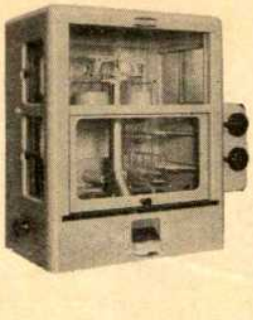
New Features – **Vernier Scale — Partial Release**



STANTON ULTRAMATICS

Four models now available, all incorporating facilities for tare weighing and partial release. New numbered Vernier Scales on Models U.M.3 and U.M.10, for greater convenience and quicker weighing.
Capacity 200 g. Sensitivities 0.1 mg–1 mg.

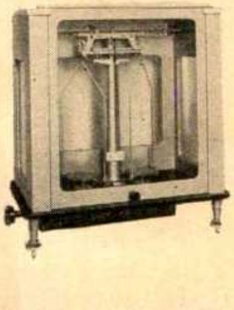
New Feature – **Twin Bankweight loading**



STANTON B.20

A worthy successor to Britain's first full Weight-loading Balance, this model now incorporates a new graticule and twin bank weight-loading, for greater convenience and quicker weighing.
Capacity 200 g. Sensitivity 0.1 mg.

And still the best value obtainable -



STANTON C.26

A firm favourite in schools and University Laboratories, where accuracy, dependability, and robustness are the key requirements.
Capacity 200 g. Sensitivity 0.1 mg.

TWO WAYS OF OBTAINING DISTILLED WATER

THE OLD

High cost — increased transport charges — bulk storage and inconvenience.

THE NEW

The C.T.P. 'Deminrolit' plant above produces approximately 300 gallons hourly of distilled quality water without using heat or steam. Operating by Ion Exchange, C.T.P. 'Deminrolit' plants occupy little space, are simple to operate and ensure a demineralised water of consistent quality.

PERMUTIT 'DEMINROLIT'

THE PERMUTIT COMPANY LIMITED, Dept.V.H.290, Permutit House, Gunnersbury Avenue, London, W.4. Telephone CHIswick 6431

to insulin) these differences were highly significant ($\chi^2 = 16.82$, $P < 0.001$), and the same is true for the combination of probabilities for experiments 1, 2 and 3 ($\chi^2 = 30.31$, d.f. $= 6$, $P < 0.001$).

Our results demonstrate clearly that between 4 and 8 days of incubation a change occurs in the reactions of the developing chicken embryo to combined treatment with insulin and cortisone. The older embryos survive better, show less retardation of growth and a lower incidence of skeletal malformations. These differences in response presumably are a reflexion of the homœostatic forces which the incipient functioning of the endocrine systems brings into play. Our observations, secondly, confirm the report by Lunardo and de Bastiani that cortisone does *not* potentiate the teratogenic action of insulin. Since our earlier experiments with an extract of adrenal cortex produced very striking potentiation, it must be concluded that this was due not to 17-hydroxy-11-dehydrocorticosterone (cortisone) but to one or more of the other corticosteroids contained in the extract. This we hope to verify in future experiments.

MATERNAL CONTROL OF OVARIOLE NUMBER IN THE PROGENY OF THE MIGRATORY LOCUST

By F. O. ALBRECHT
Laboratoire d'Evolution des Etres Organisés, Paris

M. VERDIER
Laboratoire de Biologie Animale, Paris

AND

R. E. BLACKITH
Imperial College Field Station, Sunninghill, Berks

AN integral part of the phase theory of locust transformations is the cumulative transmission of phase characters from one generation to another, so that fully *gregaria* or *solitaria* types can be obtained only when crowding or isolation of the locusts is maintained for several generations. The transmission of phase status to the progeny is held to occur through the accumulation of extra-chromosomal materials in the egg[1]. Early criticisms, understandably in view of the specific status given to the phases previously, held that they were genetically distinct but formed hybrids.

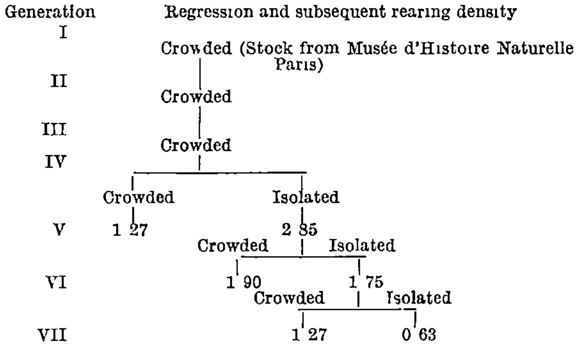
The weight of field and laboratory evidence has now accumulated to the point where the essentially non-genic nature of this inheritance is taken for granted, although the capacity of expressing it depends patently on the genotype concerned. This striking illustration of what Thoday[2] has called phenotypic flexibility has received scant notice save for some remarks of Kennedy[3,4].

Hunter-Jones[5] has shown that crowded female desert locusts, reproducing parthenogenetically, produce offspring which in colour and weight are typically *gregaria* whereas the same stock of females, when isolated, give *solitaria*-type larvæ. Our experiments show that telotykous parthenogenesis also occurs with the migratory locust, *Locusta migratoria migratorioides* R. and F. Moreover, the number of ovarioles in female offspring of isolated unfertilized females ranges from 95 to 105, whereas hatchlings from crowded mothers carry only 75–85 ovarioles. We may look to the female reproductive system for some of the clues to this problem.

There seem, in fact, to be two physiological processes at work; one of these operates through the vitellus of the egg, the reduction of which by ligaturing after blastokinesis produces larvæ which have the *solitaria* coloration (pale green) from crowded stocks of the migratory locust, the normal larvæ of which would be black and heavy[6]. Generally, weight and colour are closely associated[5], both with one another and with the subsequent rate of development and number of moults of some species of locust[7,8]. The number of ovarioles borne by these ligatured larvæ is, on the contrary, typical of *gregaria* populations. Thus the inheritance of this important phase character[9] seems to be independent of the amount of vitellus remaining in the egg. This distinction, however, may prove to be one of the timing of the processes of ovary formation and larval coloration; in *Melanoplus* and *Drosophila* at least, ovariole number seems to be determined prior to or during blastokinesis[10,11].

Table 1. MEAN REGRESSIONS OF OVARIOLE NUMBER ON HATCHLING WEIGHT OF THE MIGRATORY LOCUST, REPRESENTING THE INCREASE OF POTENTIAL REPRODUCTIVE CAPACITY FOR A SACRIFICE OF 1-MGM. WEIGHT AT BIRTH

(Standard errors of regression coefficients about 0.25 throughout)



There is in general an inverse relation between weight at hatching and the number of ovarioles in locust larvæ[9,12]. The interlocking of these two characters depends on the consistency with which the earlier generations have been kept crowded or isolated. To the extent that we may think of this relationship as a measure of the interchangeability of reproductive potential (number of ovarioles) and larval mobility (weight of occluded food reserves) the changes of its magnitude are of interest whatever the mechanism of inheritance Table 1 shows the mean regressions of ovariole number on hatchling weight for comparisons made among larvæ issuing from one and the same egg-pod Each pod contains up to 100 eggs derived from a single ovarial cycle in the female Comparisons across egg-pods or across the progeny from different females are swamped by extraneous sources of variation which themselves depend on the consistency of ancestral density Generation VI (crowded grand-parents, isolated parents) were 67 times as variable as generation VII, for which isolation was the parental and grandparental regime Yet even generation VII was 9 times as variable, as a whole, than were contrasts made within egg-pods as are those in Table 1 these varied in precision scarcely at all throughout the experiment

Crowding leads to a cumulative gain in weight at hatching for a given sacrifice of reproductive potential, and since this sacrifice has evidently not entirely been made good even three generations after crowding was ended we have the longest reach, of any yet recorded, of a density-dependent effect being transmitted to the descendants of the crowded generation Similar inheritance has, however, been demonstrated in the shorter run with other characters[6,7] In a general and less-precise way this inverse relation may be extended to fully *solitaria* and *gregaria* females, the progeny of the *gregaria* are fewer and heavier, and have fewer ovarioles compared with the progeny of *solitaria*, nevertheless, both phases produce about 1 gm of living material in each egg-pod

Setting Limits to Selective Action during the Egg Stage

Our series of 6,000 preparations of the dissected ovaries of several generations of the migratory locust affords an opportunity to set limits to the action of any selective forces operating during the development of the eggs, for the number of ovarioles in the laying female is the upper limit to the number of her progeny from which the issue of any one egg-pod can have been selected, always excluding the possibility of pre-ovogenetic selection In particular, the sequence of egg-pods laid by isolated females was studied either when the female was left with the male after copulation for the rest of her life, when the number of ovarioles in her progeny steadily diminished, or when the male was removed after 24 hr in the cage, to allow copulation to occur, when no such diminution was observed The influence of the male, once fertilization has been accomplished, is mildly to disturb the female and to induce a modest amount of those inhibitory effects normally associated with crowding The mean ovariole number of offspring from a female left with one male drops by one ovariole for each of the 15 or so reproductive cycles that the female undergoes More drastic crowding augments this progressive loss but also shortens the sequence of reproductive cycles so that the net effect is not greatly different

'Crowding' the females with a single male produces offspring of which the mean number of ovarioles eventually lies outside the range of the phenotypes initially produced by the same mating pair At most, less than half this cumulative shift can be attributed to selection, and in fact there is no evidence that any of it is so induced The absence of such a shift, in females from whom the male is removed within a few hours of copulation, excludes any influence of age alone on the mother

Regulation of Fertility and Fecundity in the Migratory Locust

Implicit in the phase theory of locust outbreaks is some autoregulation of fertility or fecundity according to the population density Our results provide some idea of the nature of such regulation in the migratory locust, other species seem to differ in important respects, and caution is needed in extending these findings to them

The influence of crowding operates both within and between generations The distinction between larval and adult crowding is vital for these comparisons, since changes of density rather than the level of the density seem to elicit the regulatory processes Crowding during the larval instars almost doubles the number of egg-pods laid by the ensuing adult females, whereas adult crowding inhibits the laying female either from fulfilling her potential delivery of egg-pods or from endowing her female offspring with their appropriate complement of ovarioles In this way larval and adult crowding act in opposite directions, and may substantially nullify one another during consistent crowding Yet when the larvæ are crowded and the adults isolated, as occurs with stragglers from gregarious groups, as many as 1,500 eggs may be laid by each female, when the reverse regime is imposed, only about a tenth of this number is to be expected

However clearly one may recognize that these ideas relate only to a few aspects of a much wider problem, the control of fecundity in the migratory locust may be regarded as a homœostatic mechanism tending to stabilize population density In every generation we have found a significant negative regression of ovariole number on hatchling weight, which we interpret as a latent ability to exchange larval food reserves for reproductive capacity When grouped locusts are dispersed, this adjustment is called into play and only fades away when several generations of isolation have failed to restore the population density through an increase in fecundity of the offspring The last word in these matters often lies with the climate, which can override the locusts' best endeavours at regulation[13]

Generally, it appears that the ability to produce offspring, the average fecundity of which is well outside the phenotypic range of the parents, lies at the heart of the capacity of migratory locusts to cope with rapidly changing environments An analysis of growth and of moulting polymorphism in the red and desert locusts led us to conclusions in the same vein[8] A full account of the experiments on which the present conclusions are based is being published[9]

SUPPLEMENT No 2

NATURE
A WEEKLY JOURNAL OF SCIENCE

LECTURES AND COURSES

HUDDERSFIELD COLLEGE OF TECHNOLOGY

REGIONAL COLLEGE
DEPARTMENT OF CHEMISTRY, COLOUR CHEMISTRY AND DYEING
Head of Department
E Tittensor, B Sc , Ph D , F R I C
DIPLOMA IN TECHNOLOGY

The four year Sandwich Course in Chemical Technology leading to the Diploma in Technology, has a special bias towards the large scale manufacture of organic compounds, contains an appreciable study of Chemical Engineering, and is specially designed for students wishing to make a career in the chemical industry Entrants (either industry based or college based) should have either (a) G C E Advanced level in Chemistry and Physics, with Mathematics and two other subjects at Ordinary Level, or (b) a good Ordinary National Certificate in Chemistry or Applied Chemistry

The Royal Institute of Chemistry has approved the course for exemption purposes on the same basis as a University Degree, and students obtaining the Diploma in Technology with First or Second class honours may apply for exemption from the whole of the Grad Mem R I C examination

Further particulars and forms of application may be obtained from the Principal of the college

H GRAY,
Chief Education Officer

CHELSEA COLLEGE OF SCIENCE AND TECHNOLOGY

MANRESA ROAD, S W 3
DEPARTMENT OF CHEMISTRY
SESSION 1959-60
Head of Department J F J Dippy, D Sc , F R I C

Recognized Day and Evening Courses leading to the B Sc General degree (London, Internal), and the Graduateship and the Diploma (Food and Drugs) of the Royal Institute of Chemistry, commence on Monday, September 28, 1959 Various postgraduate courses are also available

Full particulars on application to the Secretary

WOOLWICH POLYTECHNIC

DEPARTMENT OF MATHEMATICS
M Sc COURSE

Applications are invited from suitably qualified candidates for a one-year full-time course leading to the M Sc degree in Mathematics

The Department offers courses in the subjects (a) Functions of Mathematical Physics (b) Elliptic Functions (c) Hydrodynamics (d) Electromagnetic Theory, (e) Elasticity and Plasticity, of which two must be studied

The Department of Scientific and Industrial Research has accepted this course as suitable for the tenure of its Advanced Course Studentships Applications should be made both for the course and the studentships to the Head of the Mathematics Department as soon as possible

CHELSEA COLLEGE OF SCIENCE AND TECHNOLOGY

DEPARTMENT OF CHEMISTRY
ANALYTICAL METHODS

A second series of postgraduate lectures on more recent analytical techniques will be held during the Autumn term on Tuesdays at 7 15 p m , commencing on October 20th, 1959 The topics will include mass spectrometry, non-aqueous solvents, activation analysis, complexometric titrations, EMR and microwave spectroscopy, ion exchange, X-ray fluorescence, and gas chromatography

A leaflet giving full details, and an application form may be obtained from the Head of the Chemistry Department, Chelsea College of Science and Technology, Manresa Road, London, S W 3

COVENTRY TECHNICAL COLLEGE

Principal A J Richmond, B Sc (Eng)(Lond), Ph D , M I Mech E
SANDWICH COURSE FOR GRADUATE MEMBERSHIP OF THE ROYAL INSTITUTE OF CHEMISTRY
SESSION, 1959-60

Applications are invited for a Sandwich Course of one year and two terms duration providing for twenty weeks of full-time study in each of two sessions in preparation for Part II Grad Mem R I C Candidates should already possess Part I, or expect to gain exemption this summer Industrial training is an integral part of this course for which both works-based and college-based students may be accepted In the latter case, the College is in a position to arrange industrial training locally for suitable applicants who can then apply for a Local Authority Award to cover the cost of maintenance for the College part of the course

Further particulars may be obtained from the Head of the Chemistry Department to whom applicants should write as soon as possible giving full details of their previous education

CITY OF LEICESTER EDUCATION COMMITTEE

LEICESTER COLLEGE OF TECHNOLOGY AND COMMERCE
Principal R E Wood, M Sc , F Inst P
Registrar A Martin, F C I S
SCHOOL OF CHEMISTRY
Head L P Priestley, B Sc , F R I C
POST-GRADUATE DIPLOMA IN RADIOCHEMISTRY
In charge of Course
R W C Broadbank, B Sc , Ph D , A R I C

THIS COURSE HAS BEEN ACCEPTED BY THE DEPARTMENT OF SCIENTIFIC AND INDUSTRIAL RESEARCH AS SUITABLE FOR THE TENURE OF ITS ADVANCED COURSE STUDENTSHIPS

A full-time post-graduate course in Radiochemistry will be held (Application for approval has been made to the Ministry of Education), from 1st October, 1959 to 31st December, 1960 This course will initially provide a general basic training in radio-isotope laboratory techniques, followed by more advanced training, with special emphasis on radiochemistry as a tool for research

The Post-Graduate Diploma (in Radiochemistry) of the College will be awarded to those students completing the course, who reach the required standard in a written examination and who submit a satisfactory dissertation and thesis on a topic allocated for study and research during the course

Qualifications for admission are a Degree in Chemistry or Grad Mem R I C or B Pharm (Hons), preferably with Chemistry to Part II Number of places available is limited so that individual attention can be given to each student Early application is desirable

Further particulars may be obtained from the Head of the School of Chemistry, Leicester College of Technology and Commerce, Leicester

UNIVERSITY OF BIRMINGHAM

FACULTY OF COMMERCE AND SOCIAL SCIENCE
NOTICE TO GRADUATES AND THOSE ABOUT TO GRADUATE IN SCIENCE

The Faculty offers a one year course for graduates wishing to prepare for a career in management, leading to the Graduates' Commerce Diploma

Applications for admission to the course starting in October, 1959, and requests for further information, should be made as soon as possible to the Registrar, University of Birmingham, Edgbaston, Birmingham, 15

The Department of Scientific and Industrial Research has accepted this course as suitable, in the case of candidates with honours degrees in Science, for the tenure of its Advanced Course Studentships

NETWORK FORMATION IN VULCANIZATION

A five-day course of lectures and practical work at post-graduate level on the investigation of cross-linking processes and the structure of cross-linked rubbers

September 21–25, 1959, inclusive

For details apply to National College of Rubber Technology, Holloway Road, London, N 7 Tel NORth 4231

BATTERSEA COLLEGE OF TECHNOLOGY

BATTERSEA COLLEGE OF TECHNOLOGY, London, S W 11 Physics Department The next series of lectures on MICROWAVE PHYSICS will begin on Monday, 5th October, 1959, at 6 30 p m The Course will deal with microwave theory, techniques and applications and is suitable for graduates in mathematics, physics and electrical engineering Suitably qualified students may proceed, as part-time students, to the Internal M Sc degree of the University of London or the postgraduate Diploma of the College Further details and enrolment forms may be obtained from the Secretary (Microwave Courses)

OFFICIAL APPOINTMENTS

UNIVERSITY OF SYDNEY

LECTURESHIP IN ORGANIC CHEMISTRY
(MICROANALYTICAL TECHNIQUES)

Applications are invited for the above position The Lecturer will be responsible for the routine microanalytical (organic) and spectroscopic (ultra-violet and infra-red) service, the training and supervision of technical assistants, instruction in microanalysis to senior students, and the development of improved methods of microanalysis The salary for a Lecturer is within the range £A1,500 by £A90 to £A2,100 per annum, plus cost of living adjustment, and will be subject to deductions under the State Superannuation Act The commencing salary will be fixed according to the qualifications and experience of the successful applicant Under the Staff Members' Housing Scheme in cases approved by the University and its Bankers, married men may be assisted by loans to purchase a house

Further particulars and information as to the method of application may be obtained from the Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W C 1 Applications close in Australia and London on September 5th, 1959

UNIVERSITY OF BRITISH COLUMBIA

DEPARTMENT OF PHYSICS

The University has a vacancy for an experimental solid state physicist to head a small group working on the optical properties of semi-conductors and photo-conductors and other effects involving infra-red radiation The appointment will be made at the Assistant Associate or Full Professor rank at a salary varying from $7,500 to $12,000 depending upon qualifications There will also be financial assistance for travelling to Canada The undersigned will be in Great Britain from September 1st to 5th to interview anyone interested Address c/o B C House, London, S W 1 Write for further particulars to

G M SHRUM,
Head, Department of Physics

UNIVERSITY OF LONDON

READERSHIP IN INORGANIC CHEMISTRY AT BIRKBECK COLLEGE

The Senate invite applications for the Readership in Inorganic Chemistry tenable at Birkbeck College (salary £1,475 to £1,775 to £2,150 a year plus £80 London Allowance)

Applications (10 copies) must be received not later than 15th September, 1959, by the Academic Registrar, University of London, Senate House, W C 1, from whom further particulars may be obtained

ROYAL NAVAL SCIENTIFIC SERVICE

Vacancies for Senior Scientific Officers and Scientific Officers in following localities

London Area Mechanical Engineer with sound knowledge of basic principles of thermo and fluid dynamics to carry out research programme in a particular field of applied hydrodynamics Experience in modern methods of design and research on axial flow compressors, turbines or pumps an advantage Mechanical Engineer for work on propulsion problems Applied Mathematician for research of basic nature on stability of underwater vehicles knowledge of theoretical hydrodynamics and theory of control systems an advantage Applied Mathematician or Theoretical Physicists for acoustic analysis Electronic Physicists for data handling and analysis problems Physicist interested in operator performance Classical Physicists

Baldock Physicists or Applied Mathematicians for research in Metal or Quantum Physics

Portsmouth Electronic Engineers for research on analogue computers and transistor circuits Electrical Engineers for research on small rotating electrical machinery Physicists—for optical systems and instrumentation Electro-mechanical engineers—for work on servo-mechanisms

Portland Physicists or Applied Mathematicians for research on underwater acoustics Electronic Physicists, Electronic Engineers—for design work Physical Chemists

Poole Chemical Engineers Chemists for work on rubber technology

Rosyth Physicists—(Electronic)

Candidates must normally be natural born British subjects of natural born British parents, with first- or second-class honours degrees Senior Scientific Officers must have had three years' postgraduate experience and be not less than 26 years of age Salaries (men) Senior Scientific Officer, £1 233 to £1 460 , Scientific Officer, £655 to £1,150 (London), somewhat lower in provinces Appointments unestablished (with F S S U benefits), but opportunities may occur for those between ages of 21 and 32 to compete for established posts —Forms from Ministry of Labour and National Service, Technical and Scientific Register (K), 26 King Street, London, S W 1 (quote A 220/9A)

BOROUGH POLYTECHNIC
BOROUGH ROAD, LONDON, S E 1

Principal James E Garside, M Sc Tech , Ph D , F R I C , F I M , F Inst F

The governors invite applications for the following new appointments

DEPARTMENT OF CHEMISTRY AND FOOD TECHNOLOGY

Head of Department
Francis Aylward, Ph D , D Sc , F R I C

Lecturer in Physical Chemistry—Candidates should have good acedamic qualifications, teaching experience and/or research experience Excellent research facilities available

Lecturer in Chemical Engineering—Candidates should possess good academic qualifications in chemical engineering, chemical technology, or physical chemistry, and preferably should have had industrial and/or teaching experience

The Lecturer appointed will be expected to—
(a) Take charge of the development of Chemical Engineering Courses
(b) Assist with Courses leading to the Diploma in Technology

Good research facilities available

Salary scale £1,200 by £30 to £1,350 per annum Successful candidates may be appointed at a point on the scale above the minimum if they have had previous experience in the grade for which they have applied or in some capacity which can be regarded as equivalent

In addition, London allowance of £36 or £48 is payable and the gross salary is augmented by 5 per cent special addition

Further particulars and Form of Application, which should be returned as soon as possible, obtainable from the undersigned

FREDK J PACKER
Clerk to the Governing Body

McGILL UNIVERSITY
DIRECTOR FOR THE COMPUTATION CENTRE

The centre is equipped with an I B M 650 Preference will be given to applicants with a wide scientific background Salary $11,000 Personal details should be sent to the Vice Principal, McGill University, Montreal, Quebec

---

EAST AFRICA HIGH COMMISSION
METEOROLOGIST, EAST AFRICAN METEOROLOGICAL DEPARTMENT

Qualifications Honours degree in mathematics and/or physics Preference will be given to candidates with a post-graduate qualification and/or experience in meteorology, but this is not essential A successful applicant with no previous forecasting experience will normally be required to pass a training course

Age 21 to 35 but experienced candidates up to 45 would be considered

Duties Mainly chart analysis and weather forecasting but the officer may be required to undertake research

Terms of Appointment On probation to the permanent and pensionable establishment, or on contract for one tour (30–36 months) in the first instance with gratuity on satisfactory completion of service Salary in the scale £939–£1,863 per annum Outfit allowance Free passages Quarters provided at rental if available House or hotel allowance if quarters not provided Generous leave Medical attention available Taxation at local rates

Apply to Director of Recruitment, Colonial Office, London, S W 1 State full name, age, qualifications and experience Quote BCD/57/88/01/C1

TEHERAN UNIVERSITY
TECHNICAL FACULTY

Applications are invited for lectureships in WORKSHOP TECHNOLOGY, CHEMICAL ENGINEERING, ELECTRICAL ENGINEERING, MECHANICAL ENGINEERING AND GEOLOGY

Candidates must be British subjects with British University or equivalent qualifications and laboratory experience

Salary free of tax £2,750 a year plus free accommodation Contract for one year, renewable Return fares paid, also for family U K superannuation may be maintained and secondment from present employment might be arranged

Write, quoting N7(59) and enclosing stamped, addressed foolscap envelope to Director, Recruitment Department, British Council, 65 Davies Street, London, W 1 , for further particulars and application form, to be returned, completed, within two weeks of receipt

---

UNIVERSITY OF NATAL
SOUTH AFRICA
DEPARTMENT OF BOTANY

Applications are invited from suitably qualified persons for appointment to the post of Lecturer in Botany, Pietermaritzburg An interest in Algae and Fungi is desirable

The salary scale attached to the post is £1,050 by £60 to £1,530 per annum The commencing notch on the above salary scale will be dependent on the qualifications and/or experience of the successful candidate

Application forms and further particulars of the post, including commencing dates, etc , are obtainable from the Secretary, Association of Universities of the British Commonwealth, 36, Gordon Square, London, W C 1

Applications close in South Africa and London on 31st August, 1959

NORTHERN POLYTECHNIC, HOLLOWAY, LONDON, N 7

The Governing Body invite applications for the post of Senior Lecturer in Inorganic Chemistry to commence in January, 1960 Experience in teaching and research essential Industrial experience would be an advantage The candidate appointed will be expected to initiate and direct research in his special subject Salary scale Men—£1,417 10s by £52 10s to £1,627 10s , Women—£1,336 10s by equal pay increments to £1,627 10s , together with allowances in accordance with the Burnham Award

Form of application and further particulars will be sent on request to the Clerk to the Governors

---

UNIVERSITY OF BIRMINGHAM
DEPARTMENT OF CHEMISTRY

Applications are invited for a National Coal Board Postdoctoral Fellowship in Physical Chemistry The research work to be undertaken is connected with the study of solids by a number of techniques such as mass spectroscopy The salary will be £700 to £800 per annum according to age and experience

Applications (two copies) should be sent as soon as possible to the Deputy Registrar, The University, Edgbaston, Birmingham, 15

KING'S COLLEGE HOSPITAL
DENMARK HILL, S E 5

Applications are invited for an appointment as Senior Assistant Physicist The successful candidate will be expected to take responsibility in radiation physics and isotope work, and hospital experience is desirable He will have an opportunity of partaking in other branches of medical physics work including some research Salary according to Whitley Council scales for the Senior Grade £1,190 to £1,600, including London Weighting

Applications, together with the names of two referees, should be sent to the House Governor, King's College Hospital, Denmark Hill, London, S E 5

S W BARNES,
House Governor

GOVERNMENT OF TANGANYIKA
GEOLOGIST

Qualifications First or good Second-class honours degree in Mining Geology Post-graduate experience desirable Candidates with a First or good Second-class honours degree in geology and post-graduate experience in mining geology will be considered

Age Preferably under 35

Duties Regional mineral survey, detailed examination of producing mines and mineral prospects

Terms of appointment On probation to the permanent and pensionable establishment, or on contract for one tour (30–36 months) in the first instance with gratuity on satisfactory completion of the engagement Emoluments in the scale £981–£1,863 per annum Outfit allowance Education allowances for children Subsistence and transport allowances when travelling on duty Free passages Quarters provided if available at rental Generous leave Taxation at local rates Free medical attention

Apply to Director of Recruitment, Colonial Office, London, S W 1 State full name, age qualifications and experience Quote BCD 105/8/03/C1

WELSH PLANT BREEDING STATION
UNIVERSITY COLLEGE OF WALES
ABERYSTWYTH

Applications are invited for an officer with special interest in abstracting and translating to take charge of the Library of the Welsh Plant Breeding Station For further particulars apply to the Secretary, Welsh Plant Breeding Station, Plas Gogerddan, Near Aberystwyth

---

BOTANY SCHOOL, OXFORD

Cytologist wanted to carry out experimental research with chromosomes under a D S I R grant tenable for three years under the present grant, beginning at any convenient time Candidates should hold a Doctor's degree and the salary will be in the range of £800–£1,100 plus F S S U Applications should be sent to the Sherardian Professor

---

AUSTRALIAN NATIONAL UNIVERSITY
CANBERRA
RESEARCH SCHOOL OF PACIFIC STUDIES
READERSHIP OR SENIOR FELLOWSHIP IN BIOGEOGRAPHY

Applications are invited for appointment to a Readership or Senior Fellowship in the Department of Geography The qualifications desired are essentially in plant ecology, and tropical experience would be an advantage The status of the appointment made will be in accordance with qualifications and experience

The salary for Readers is within the range £A2,763–£A3,213 A Reader is appointed to the permanent staff, retiring age is sixty-five with the option of retiring after the age of sixty Senior Fellows are appointed at a salary in a range fixed within the limits £A2,553–£A3,063 and appointment is made for an initial period of five years, thereafter it may be made permanent

The person appointed will be entitled to one year's study leave on full pay plus a contribution of up to £A1,342 (if a Reader) or £A1,226 (if a Senior Fellow) towards travel and other expenses, in every six years

Superannuation on the F S S U pattern is provided and reasonable removal expenses are paid

Further details are available from the Secretary, Association of Universities of the British Commonwealth, 36, Gordon Square, London, W C 1

Applications close in Australia and London on 15th October, 1959

STUDLEY COLLEGE, WARWICKSHIRE

AGRICULTURAL AND HORTICULTURAL COLLEGE FOR WOMEN

Principal Miss E E Hess, N D H

Applications are invited for the post of Assistant Lecturer in Agriculture to Diploma standard, from single or married men and women, with a degree in agriculture and/or N D A Some experience in practical farming and teaching

Salary will be on one or other of the following scales plus 5 per cent Farm Institute Scale Grade II (Men) £550 to £975 or Further Education Scale Assistant Grade B (Men) £650 to £1,025

Applications giving age, qualifications, experience, etc , and two referees to the Principal as soon as possible

---

RADIOLOGICAL PROTECTION SERVICE (Medical Research Council and Ministry of Health), Clifton Avenue, Belmont, Sutton, Surrey, requires a Scientist with First or Second class Honours degree, to join a team of physicists and engaged chemists on problems concerned with the hazards to human beings from internally deposited radioactive materials The work will be mainly concerned with the evaluation of maximum permissible amounts of various isotopes in human beings and the measurement of body radioactivity by excretion methods Preference will be given to persons having an interest and training in both physics and biology

Salary according to age and qualifications at a point on the scales £750 by £50 to £850 or £900 by £100 to £1,100 per annum, plus London Weighting and child allowances

Applications with the name and address of two referees, to the Director, Mr W Binks, at the above address

---

NATIONAL INSTITUTE FOR RESEARCH IN DAIRYING

(UNIVERSITY OF READING)

Appointment for approximately 5 years for research scientist to work on project administered under U S A Counterpart Funds Project includes application of new techniques in differentiation and recognition of strains of micro-organisms important in dairy products with aim of obtaining data useful in scientific control of manufacturing procedures Candidates should possess first or good second class honours in chemistry or biochemistry Some experience or training in bacteriology an advantage Starting salary, according to experience in the range £650–£1,120 p a Superannuation under F S S U Applications naming two referees and stating full particulars to the Secretary, N I R D Shinfield, Reading, Berks *Quoting ref* 59/8

CIVIL ENGINEERS FOR DEPARTMENT OF MAIN ROADS, NEW SOUTH WALES, AUSTRALIA

Applications are invited from graduates (or undergraduates in their final year) in Civil Engineering of a recognised British or Irish University for appointment to the staff of the Department of Main Roads, New South Wales, the State Road Authority for construction of roads and bridges

On appointment, applicants may be engaged at the Department's Head Office, Sydney, on the design of reinforced concrete and steel bridges, or on main road construction and maintenance either in the Metropolitan Area or the country

Commencing salary according to qualifications and experience will be within the range £A1,185 to £A1,410 per annum, with annual progression, subject to technical competence to £A2,095 per annum Appointees will be eligible to contribute to the State Superannuation Fund after six months

Appointee's full fare from England to Australia will be met by the Department, subject to a three years' service guarantee bond being completed Appointment will be subject to passing a medical examination and preference will be given to applicants not more than 30 years of age

Applications should be made on forms obtainable from the Agent General for New South Wales, 56 Strand, London, W C 2

UNIVERSITY OF GLASGOW

Research Assistant required to work on the effects of low temperature on mice Candidates should have a good degree in Zoology or Physiology Starting date as soon as possible Appointment in the first instance to 30th September, 1960 Salary not more than £650 per annum Applications, giving the names of two referees, should be sent at once to Dr S A Barnett, Zoology Department, The University, Glasgow, W 2

UNIVERSITY OF EDINBURGH

DEPARTMENT OF ENGINEERING

Applications are invited for the post of Assistant in the Department of Engineering Salary Scale £700 by £50 to £850 per annum, together with superannuation benefit and family allowance where applicable Candidates are normally expected to possess an honours degree in Mechanical or Civil Engineering The successful candidate will be encouraged to research with a view to obtaining a higher degree

The successful Candidate will be expected to take up duty on 1st October, 1959

Further information may be obtained from the undersigned, with whom applications, giving the names of two referees, should be lodged as soon as possible

CHARLES H STEWART,
Secretary to the University

COMMONWEALTH AGRICULTURAL BUREAUX

Applications are invited for the post of—

DIRECTOR, COMMONWEALTH BUREAU OF ANIMAL NUTRITION, ROWETT RESEARCH INSTITUTE, BUCKSBURN, ABERDEEN, SCOTLAND

The work of the Bureau is to collect, collate and make available to research workers information on the nutrition of man and animals and its implications for agriculture and human welfare Salary scale £2,200–£2,600 Provision for superannuation

Applications should be submitted by 31st October, 1959, to the Secretary, Commonwealth Agricultural Bureaux, Farnham House, Farnham Royal, Bucks , from whom full particulars, including regulations for passages to overseas candidates on first appointment, can be obtained Government employees should apply through their governments

---

UNIVERSITY OF NEW ENGLAND AUSTRALIA

TWO LECTURESHIPS IN GEOGRAPHY

Applications are invited for two positions of Lecturers in Geography These are new appointments to meet demands of increases in numbers of students Duties will include work with both internal and external students, but a substantial part of the work will be with external students by correspondence and at residential schools

Commencing salary will be determined according to qualifications and experience within the range £A1,500 by £A90 to £A2,100 plus cost of living allowance Provision is made for superannuation, travel and removal expenses, assistance in buying or building a house

Further information may be obtained from the Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W C 1

Applications close, in Australia and London, on 15th September, 1959

FISHERIES RESEARCH BOARD OF CANADA

A shellfish biologist is required for oyster research in eastern Canada probably with headquarters at Ellerslie, Prince Edward Island To be considered, an applicant must have a Bachelor s degree, or better, with biological training and ability to organize work and supervise subordinates The position will be classified Assistant Scientist ($4,600 to $5,800) or Associate Scientist ($6,000 to $7,500) according to the qualifications and experience of the successful applicant The Fisheries Research Board of Canada is an agency of the Government of Canada and service with it carries all the privileges (leave, superannuation, death benefit) of Public Service

Applications should be accompanied by statements of personal history and training and recommendations from former employers and professors, and addressed to the Director, Fisheries Research Board of Canada, Biological Station, St Andrews N B , Canada

---

UNIVERSITY OF DURHAM

KING'S COLLEGE, NEWCASTLE UPON TYNE

Department of Physics

A TECHNICIAN

required in the Department of Physics Experience with lecture demonstrations an advantage but not essential Commencing salary at an appropriate point on the Technicians' Scale (£440–£590) depending on age, qualifications and experience

Applications, giving full details of qualifications and experience should be addressed to the Professor of Physics, King's College, Newcastle upon Tyne, 1

UNIVERSITY OF DUBLIN

TRINITY COLLEGE

Applications are invited for the following posts in the School of Veterinary Medicine, duties to be taken up on January 1st 1960

Senior Lecturer in Bacteriology and Pathology
Senior Lecturer in Surgery
Lecturer in Biochemistry
Lecturer in Pharmacology
Lecturer in Bacteriology and Pathology
Lecturer in Animal Husbandry
Lecturer in Obstetrics

For the Lectureship in Biochemistry a Veterinary qualification is desirable, for all other posts a Veterinary qualification is essential

Salary scales Senior Lecturers £1,370–£1,775 (with increments of £135 at 10, 15 and 20 years), Lecturers £1,045 by £47 10s to £1,377 10s by £23 15s to £1,520, with membership of a non-contributory Superannuation and Life Assurance Scheme

Applications (three copies), stating experience and the names and addresses of three referees, should reach the Registrar, Trinity College, Dublin, from whom further particulars may be obtained, not later than September 30th, 1959

UNIVERSITY OF EDINBURGH

DEPARTMENT OF CHEMISTRY

Applications are invited for the post of Assistant in the Department of Chemistry Salary Scale £700 by £50 to £850 per annum, with superannuation benefit and family allowance where applicable Tenure is normally for three years The successful candidate will be expected to take up duty on 1st October, 1959

Further particulars may be obtained from the undersigned, with whom applications, giving the names of two referees, should be lodged as soon as possible

CHARLES H STEWART,
Secretary to the University

CRUMPSALL HOSPITAL, MANCHESTER, 8

Applications are invited for the post of —

RESEARCH BIOCHEMIST

in the Department of Pathology, Crumpsall Hospital

Applicants should hold an honours degree in Chemistry or Biochemistry, or be Associates of the Royal Institute of Chemistry Previous hospital experience not essential

The appointment will be in the basic grade of the N H S scales for Biochemists and will be for a period of three years

Applications, together with the names and addresses of two referees should be sent to the Hospital Administrator, Crumpsall Hospital, Manchester, 8

LONDON COUNTY COUNCIL

NORWOOD TECHNICAL COLLEGE

CHEMISTRY AND BIOLOGY DEPARTMENT

Research Assistant (Plankton), full time, required September, 1959, for two years (extension to three possible), to join small team (in association with N Z Institute of Oceanography) working on Plankton from waters south of New Zealand Work suitable for London University external M Sc or Ph D Applicants should be Zoology graduates (or taking Finals this year) with real interest in Plankton

Allowance £300 per annum (subject to review) plus about £150 per annum for about six hours teaching a week

Application forms from Principal at College, Knight's Hill, London, S E 27, to be returned within 14 days (1406)

DERBY AND DISTRICT COLLEGE OF TECHNOLOGY

Principal T Heap, Ph D , M Sc , F R I C , A M I I A

Applications are invited from Honours Graduates in Chemistry for posts as Research Assistants Posts are tenable for two years in the first instance

The persons appointed will carry out research work for higher degrees on one of the following

1 The relationship between sorption affinity of alumina for a series of organic solutes in non polar solvents and certain physical properties of the sorptives
2 A problem in nitrogen heterocyclic chemistry

Salary scale £550 by £50 to £650

Further particulars and application forms can be obtained from the Principal, Derby and District College of Technology, to whom completed applications should be returned as soon as possible

C MIDDLETON
Secretary to the Joint Education Committee

UNIVERSITY OF BIRMINGHAM

DEPARTMENT OF INDUSTRIAL METALLURGY

Applications are invited for a Lectureship in the Department of Industrial Metallurgy to lecture to final year and postgraduate students Good facilities are provided for research Candidates should have a good degree in Metallurgy or Chemistry and industrial or research experience, ability in thermodynamics and an interest in the application of science in the field of melting and solidification would be an advantage Salary within range £900 to £1 650 with F S S U and family allowance

Applications (three copies), with the names of three referees, should be sent to the Deputy Registrar, The University, Birmingham, 15, from whom further particulars may be obtained

---

THE HOSPITAL FOR SICK CHILDREN

GREAT ORMOND STREET, LONDON, W C 1

Applications are invited for the appointment of Research Biochemist (Ph D standard) to work primarily on steroid chemistry in children The salary offered is within the range £1,190 to £1,600 per annum according to qualifications and experience Applications should be sent to Dr B Clayton, Department of Chemical Pathology from whom further particulars may be obtained

---

UNIVERSITY OF LONDON KING'S COLLEGE

The College will require on October 1st, 1959, a Lecturer in Zoology Applicants should have experience in teaching the zoology of the invertebrates to Honours standard A special interest in parasitology, genetics or cell physiology would be an advantage, but is in no way essential

Salary scale £900 by £50 per annum to £1,350, then, after review, by £75 per annum to £1,650 Starting point according to qualifications and experience A London allowance of £60, family allowances and F S S U benefits will also be payable

Full conditions of appointment and application forms may be obtained from the Registrar, King's College London, Strand, W C 2, completed forms must reach him within a fortnight from appearance of this advertisement

---

THE UNITED BIRMINGHAM HOSPITALS

THE GENERAL HOSPITAL BIRMINGHAM, 4

Technician, B Sc, or equivalent qualification Haematology Department, salary £535 to £635 per annum, and conditions of service as agreed by the Whitley Council Applications stating age and education and giving names of two referees, should be addressed to the House Governor

---

UNIVERSITY OF EDINBURGH

DEPARTMENT OF ANIMAL GENETICS

Biochemist, or other suitably qualified person, required to collaborate with Dr G H Beale in genetical and biochemical work with *Paramecium* antigens The work is concerned with gene controlled variations in protein specificity Salary in accordance with qualifications

Further particulars may be obtained from Dr Beale, Institute of Animal Genetics, University of Edinburgh, The King's Buildings, West Mains Road, Edinburgh, 9

INSTITUTE OF ANIMAL PHYSIOLOGY

BABRAHAM, CAMBRIDGE

Assistant Experimental Officer with experience of Isotope counting equipment required to undertake maintenance, development and some routine duties Minimum qualifications G C E in five subjects including two (Science or Maths) at Advanced level, or equivalent Salary according to age in scale, £427 at 19, to £855 Contributory superannuation scheme Applications with the names of two referees to the Secretary within two weeks

---

BIOCHEMIST required for research into brain metabolism, especially into the effects of stress on molecular and enzymic dynamics The work will be co-ordinated with that of a team on the cybernetic aspects of stress Initiative and adaptability are required rather than any highly specialised technique

Applicant should have a good Honours degree Facilities will be given for a Ph D thesis The appointment will be for three years in the first instance Salary in accordance with qualifications

Applications to the Director, Burden Neurological Institute, Stapleton, Bristol

---

PLANT BREEDER (PYRETHRUM), KENYA

In addition to main duties in plant breeding, he will be required to take control of pyrethrum research and be responsible for agronomic trials with pyrethrum

Candidates must have a degree in Agriculture or Horticulture or an Honours degree in Botany with post-graduate training or experience in plant breeding Training in plant breeding can be arranged for a candidate without post-graduate experience

Appointment on probation for permanent establishment with pensionable emoluments in scale £981–£1,863 per annum Free passages on appointment and leave for officer, wife and children up to three adult passages in all Furnished accommodation, if available, at moderate rental

Apply giving brief particulars, to Director of Recruitment, Colonial Office, London, S W 1, quoting BCD63/7/014

DAIRY RESEARCH INSTITUTE (N Z)

BIOCHEMIST

Applications are invited for a position as Biochemist in the Bacteriological Department of the Dairy Research Institute (N Z) Palmerston North, New Zealand Commencing salary will be within the ranges £720 to £1,000 or £1,025 to £1,275, depending on experience, qualifications and age The appointee is required for research into cheese-ripening problems, and it would be an advantage to have some experience in bacteriological technique He will probably be required to work for a period of one or two years at the National Institute for Research in Dairying, at Shinfield, Reading, before proceeding to New Zealand

Further particulars may be obtained from the Secretary (Ref 59/11), National Institute for Research in Dairying, Shinfield, Reading

---

LABORATORY STEWARD required to administer stores (including chemicals and glassware) and to service teaching laboratories, some scientific knowledge (particularly in chemistry) desirable and experience in glass-blowing an advantage Salary on scale £440–£590 Applications giving age, qualifications and the names of two referees to be addressed to Professor R D Preston, Department of Botany, The University, Leeds, 2

BIRKBECK COLLEGE

(UNIVERSITY OF LONDON)

Applications are invited from physical chemists or biochemists for a research fellowship for work on virus substructure in conjunction with a team studying the structure of viruses by physical methods Starting salary up to £1,250 per annum according to qualifications and experience Alternatively, graduates wishing to read for a higher degree might be considered for appointment to a Research Assistantship with a starting salary of up to £800 per annum

Candidates free to assume appointment on, or at any time before, October 1, 1959, should apply as soon as possible for further information to the Secretary, Birkbeck College, Malet Street, London, W C 1

NATIONAL INSTITUTE FOR RESEARCH IN DAIRYING

(UNIVERSITY OF READING)

Honours Graduate in Bacteriology, or graduate with subsequent experience in bacteriology, to assist in work on bovine mastitis, mainly using one-egg twins Opportunities to study for higher degree Appointment to either Scientific Officer Class, commencing salary range £615 to £1,166, or Experimental Officer Class, £492 to £954, according to age, qualifications, and experience, F S S U

Applications, naming two referees, to Secretary, N I R D, Shinfield, Reading Quote ref 59/12

THE ROYAL SOCIETY

FOULERTON GIFT RESEARCH FELLOWSHIP

The Council of the Royal Society invites applications from candidates of British nationality for a FOULERTON GIFT RESEARCH FELLOWSHIP for original research in medicine The stipend will be in the range from £850 to £1,050 and the appointment is for two years in the first instance from 1st January, 1960 Application forms may be obtained with further particulars from the Assistant Secretary, The Royal Society, Burlington House, London, W 1, to whom they should be returned not later than 1st October, 1959

CITY AND COUNTY OF BRISTOL

THE COLLEGE OF TECHNOLOGY

(Designated as a College of Advanced Technology as from September, 1960)

The Governors invite applications for the following posts to commence on 1st September, 1959 or as soon as possible thereafter

LECTURER IN MATHEMATICS

Applicants should possess an honours degree in Mathematics or Statistics and should have teaching and research or industrial experience involving the application of mathematics to scientific or engineering problems Preference given to candidate with experience in statistical work

ASSISTANT GRADE B IN MATHEMATICS, for work up to and including Ordinary National Certificate Applicants should possess a degree in Mathematics and should have teaching and research or industrial experience involving the application of mathematics to scientific or engineering problems

Salary Burnham Scales —

Lecturer Men, £1,260 by £31 10s to £1,417 10s, Women, £1,008 by £25 4s to £1,134 plus equal pay increments

Assistant, Grade B Men, £682 10s by £26 5s to £1,076 5s, Women, £609 by £21 to £861, plus equal pay increments

Placing on scale dependent on approved industrial and teaching experience and, in case of Grade B Assistant, there will also be additions for degree and training

Application form, *returnable within fourteen days of appearance of this advertisement*, and details from Registrar, College of Technology, Ashley Down, Bristol 7

THE ROYAL COLLEGE OF SCIENCE AND TECHNOLOGY

GLASGOW

DEPARTMENT OF CHEMICAL TECHNOLOGY

Applications are invited for

LECTURESHIP IN CHEMICAL TECHNOLOGY

from candidates possessing good Honours Degree in Chemistry, Applied Chemistry, Chemical Engineering or related subject Industrial chemical plant experience a strong qualification Other qualifications sought include a higher degree, teaching and research experience, or a mathematical bias Research work encouraged for which there are excellent facilities Salary on scale £900 by £50 to £1,350 by £75 to £1,650 Application forms from the Secretary-Treasurer, George Street, Glasgow, C 1

WOOLWICH POLYTECHNIC

Applications invited for a Research Assistant in Mathematics Department The canditate appointed will be expected to read for an M Sc or Ph D (Internal) Degree of London University in the field of Elasticity The Assistantship is tenable for two or three years and has a value of £440–£600 a year Particulars and application form from Clerk to Governors

---

McMASTER UNIVERSITY

Applications are invited for positions in Physical Chemistry and in Organic Chemistry at McMaster University, Hamilton, Ontario for September, 1959 or September, 1960 Appointments will be made at a rank and salary appropriate to qualifications Preference will be given to recent graduates with postdoctoral experience There are excellent facilities for research including a one megawatt swimming pool reactor

Inquiries should be directed to D B MacLean, Chairman, Department of Chemistry

---

UNIVERSITY OF CAMBRIDGE

SCHOOL OF VETERINARY MEDICINE

Research Assistant, science graduate, required to carry out experimental work on animal blood-groups Previous experience in serology and blood-group studies necessary

For particulars apply to the Administrative Secretary, School of Veterinary Medicine, Madingley Road, Cambridge

---

MOREDUN INSTITUTE

EDINBURGH

Experimental Officer (male) for Biochemistry Department Should have experience of biochemical research Science Degree or A R I C preferred Salary range £980 to £1,200 F S S U

Full particulars and names of two referees to The Secretary, Animal Diseases Research Association, Moredun Institute, Gilmerton, Edinburgh, 9

UNIVERSITY OF CANTERBURY

CHRISTCHURCH, NEW ZEALAND

LECTURESHIP IN CIVIL ENGINEERING

Applications are invited for the above position Applicants should have a degree in Civil Engineering of a recognised University, teaching experience at a University, or have held a responsible position in a branch of Civil Engineering The salary will be at the rate of £1,025 per annum, rising by annual increments of £50 to £1,275 per annum Commencing salary will be in accordance with qualifications and experience An allowance is made towards travelling expenses

Further particulars and information as to the method of application may be obtained from the Secretary,Association of Universities of the British Commonwealth, 36, Gordon Square, London, W C 1 Applications close in New Zealand and London on September 30th, 1959

UNIVERSITY COLLEGE OF RHODESIA AND NYASALAND

Applications are invited for a Lectureship in Botany from candidates with special interest in Plant Physiology Salary scales Assistant Lecturer £1,050 by £50 to £1,200 per annum, Lecturer (Grade II) £1,200 by £50 to £1,450 per annum, (Grade I) £1,450 by £50 to £1,750 per annum, entry point determined by qualifications and experience Superannuation Scheme Passages to Salisbury for appointee, wife and dependent children on appointment with allowance for transport of effects Unfurnished accommodation at rent of 15 per cent of salary Assistance given for triennial leave overseas

Detailed applications (six copies) naming three referees by August 30th, 1959 to Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W C 1, from whom further particulars may be obtained

---

UNIVERSITY COLLEGE, DUBLIN

Applications are invited for the post of Academic Assistant in the Department of Chemistry to hold office from October 1st, 1959 The successful candidate will be expected to have a Ph D degree, preferably on the inorganic side, and some experience in lecturing to large classes The initial salary is £850 per annum and there are prospects of promotion to Assistant—and eventually to College-Lectureships The pension scheme is non-contributory and family allowances are given Fees are paid for examination work

Further particulars may be obtained from the Secretary and Bursar, University College, Earlsfort Terrace, Dublin, who will accept applications, which should show the names of two referees, up to September 1st, 1959

UNIVERSITY OF TASMANIA

AUSTRALIA

LECTURESHIP OR SENIOR LECTURESHIP IN FLUID DYNAMICS

The University invites applications for the above position The salary grades for Lecturers are Grade II £A1,450 by £A60 to £A1,630 and Grade I £A1,630 by £A60 to £A2,050, and for Senior Lecturer £A2,150 by £A60 to £A2,510 Appointment will be offered within one of these grades according to qualifications and experience

Further particulars and information as to the method of application may be obtained from the Secretary, Association of Universities of the British Commonwealth, 36, Gordon Square, London, W C 1, Applications close in Australia and London on 14th September 1959

MEDICAL RESEARCH COUNCIL require a young graduate, with a First or good Second Class honours degree in physics, chemistry or engineering, for their PNEUMOCONIOSIS RESEARCH UNIT, Cardiff, for interesting research into the effect of environmental conditions (especially dust) on the health of workers, in collaboration with the Department of Occupational Health at the London School of Hygiene, where an initial training period will be provided Salary within range £700–£850 per annum, according to qualifications and experience Superannuation provision Apply Director, Pneumoconiosis Research Unit, Llandough Hospital, Penarth, Glamorgan

---

UNIVERSITY COLLEGE HOSPITAL MEDICAL SCHOOL

Research Assistant required in Pathology Department Graduate in biochemistry or biology Salary according to experience

Application to Secretary, University College Hospital Medical School, University Street, London, W C 1

UNIVERSITY OF BRITISH COLUMBIA

DEPARTMENT OF PHYSICS

Applications are invited for permanent and also temporary positions for the Session commencing in September, 1959 Full particulars and a descriptive booklet available upon request Applicants are requested to send information regarding training and experience The undersigned will be in London from September 1st to 4th inclusive for interviews London Address c/o B C House, 1–3 Lower Regent Street, S W 1

For further information write G M Shrum, Head, Department of Physics, University of British Columbia, Vancouver, Canada

---

NORTHERN POLYTECHNIC

HOLLOWAY, LONDON, N 7

Applications are invited from honours graduates in physics for appointment as research assistant for problems concerned with fast particle techniques, gas discharges, spectroscopy or electronics The candidate appointed can qualify by research for the Ph D degree Rate of pay—approximately £480 per annum

Further particular and form of application obtainable from the Clerk to the Governors

---

UNIVERSITY OF SOUTHAMPTON Technician or Junior Technician (male) required in the Department of Botany, to have special responsibility for mycology, with some general laboratory duties Previous experience not necessary, training in mycological techniques will be given Salary scale Technician £440 by £20 to £590 per annum, with superannuation and sick pay scheme, Junior Technician £3 14s 6d per week at 16, rising to £7 9s 6d at 23, with prospects of promotion Starting date on or after July 6th, 1959 (existing holiday arrangements will be respected)

Written applications, stating qualifications and giving the names of two referees, should be sent to the Professor of Botany, The University, Southampton, within two weeks of the appearance of this advertisement

---

WOLVERHAMPTON AND STAFFORDSHIRE COLLEGE OF TECHNOLOGY

Principal Robert Scott, M A , B Sc , Dip Ed

DEPARTMENT OF APPLIED SCIENCE

Assistant Grade B in Physics

Applicants should be honours graduates in physics, and have had suitable teaching, research or industrial experience The person appointed will be expected to teach some advanced level mathematics Experience in some branch of applied physics would be an added advantage

Assistant Grade B in Chemistry

Applicants should have a good honours degree or equivalent, together with teaching, research or industrial experience The person appointed will be required to teach inorganic chemistry to H N C and G R I C Part I standard

Salary Men, £682 10s by £26 5s to £1,076 5s per annum, Women, £609 by £21 to £861, plus equal pay additions Additions for training, degree and appropriate experience Application forms and further particular (s a e) from the undersigned, to whom applications should be returned within two weeks

G W R LINES,
Clerk to the Joint
Education Committee

Education Offices,
North Street, Wolverhampton

SWAZILAND

AGRICULTURAL RESEARCH OFFICERS

Vacancies exist for (i) Cotton and Grain Crop Research Officer for team research investigations into the agronomy of cotton and grain crops with emphasis on variety testing, (ii) Horticulture and Citriculture Research Officer for team research investigations in citriculture and horticulture with special reference to irrigated crops in a subtropical area Candidates for either post must have a university degree in Agriculture, Horticulture or Botany and preferably with some post-graduate research experience Appointments are on contract/gratuity terms but with good prospects of conversion to permanent and pensionable terms in due course Salaries are in scale £660–£1,515 plus a cost of living allowance Free passages for officer, wife and children up to equivalent of four adult passages on appointment and up to equivalent of three adult passages on leave Furnished accommodation available at moderate rental

Apply, stating name in full and giving brief details of qualifications and experience, to Director of Recruitment, Colonial Office, London, S W 1, quoting BCD 63/76/013/C1

SENIOR TECHNICIAN, HISTOLOGICAL (Category I or II according to qualifications and experience) or Technician, required in Neuropathology Department at Fountain Hospital for research into Mental Deficiency Experience in Neuropathology an advantage Salary according to qualifications and experience

Applications giving full particulars of qualifications, experience and names and addresses of two referees to be sent to Group Secretary, Fountain Hospital, Tooting Grove, London, S W 17

UNIVERSITY OF MALAYA

(SINGAPORE DIVISION)

Applications are invited for Chair of Chemistry Salary between £2,268 and £2,548 per annum, at fixed point determined by qualifications and experience Allowances expatriation £378 per annum, cost of living £210–£560 per annum Passages for appointee, wife and children under 12 years Part-furnished quarters at reasonable rent Provident Fund Scheme

Detailed applications (10 copies) naming three referees by September 30th, 1959, to Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W C 1, from whom further particulars may be obtained

---

RE-ADVERTISEMENT

HUDDERSFIELD COLLEGE OF TECHNOLOGY

Principal Dr W E Scott, M B E

DEPARTMENT OF CHEMISTRY, COLOUR CHEMISTRY AND DYEING

Required September 1st, 1959 or as soon afterwards as possible Assistant Grade "B" to assist in the teaching of Physical and Inorganic Chemistry An active interest in research, together with experience in teaching and/or industry is desirable The salary (Burnham Scale) rises to a maximum of £1,025 per annum (Women £820 plus equalisation pay), plus allowances for graduate status (£75 or £125 Men, £60 or £100 Women) and training (£25 to £75 Men, £20 to £60 Women) All amounts subject to 5 per cent special addition The commencing salary will depend upon qualifications and experience and may include up to 12 increments in respect of approved service in industry

Further particulars and forms of application, which must be returned as soon as possible, obtainable from the Principal

H GRAY,
Clerk to the Governors

UGANDA NATIONAL PARKS

VACANCY FOR DIRECTOR

Applications are invited for the post of Director of the Uganda National Parks which will become vacant on or about July 1st, 1960 Conditions and terms of service will be by arrangement but will include a salary of not less than £2,000 per annum, free housing, contributory retiring benefits, overseas leave for persons not ordinarily resident in East Africa Preference will be given to applicants with a university degree in natural science and with African experience but such qualifications will not be necessary for appointment

Applications giving details of experience and the names of two referees should be sent to the Chairman, Uganda National Parks, P O Box 50, Entebbe, Uganda, reach him before September 15th, 1959

UNIVERSITY OF CANTERBURY

CHRISTCHURCH, NEW ZEALAND

ASSISTANT LECTURER IN BOTANY

Applications are invited for the above position Candidates should have an Honours degree in Botany Preference will be given to applicants with experience in mycology, but consideration will also be given to applicants with interests in other fields The salary will be at the rate of £780 per annum rising by annual increments of £50 to £880 per annum An allowance is made towards travelling expenses

Further particulars and information as to the method of application may be obtained from the Secretary, Association of Universities of the British Commonwealth, 36, Gordon Square, London, W C 1 Applications close in New Zealand and London on September 30th, 1959

UNIVERSITY COLLEGE HOSPITAL MEDICAL SCHOOL

Experienced male technician required to assist in research project in the Department of Chemical Pathology from 1st September, 1959 Salary, Whitley Council Scales Apply in writing to the Secretary, University College Hospital Medical School, University Street, London, W C 1

UNIVERSITY OF CANTERBURY
CHRISTCHURCH, NEW ZEALAND
ASSISTANT LECTURER IN GEOLOGY

Applications are invited for the above position Candidates should have an Honours degree in Geology and be able to lecture in Historical Geology and Micro-palaeontology The salary attached to the position will be at the rate of £780 per annum rising by annual increments of £50 to £880 Commencing salary will be in accordance with qualifications and experience An allowance is made towards travelling expenses

Further particulars and information as to the method of application are obtainable from the Secretary, Association of Universities of the British Commonwealth, 36, Gordon Square, London, W C 1 Applications close in New Zealand and London on September 30, 1959

UNIVERSITY OF BRISTOL
DEPARTMENT OF CIVIL ENGINEERING

Applications are invited for a Lectureship (Grade III or II) in the Department of Civil Engineering Applicants should have a good honours degree and some practical experience, preferably in the field of structural steelwork It is desirable that candidates should be under 35 years of age and have some teaching experience Salaries will be in accordance with the following scales Assistant Lecturer (Grade III) £700 to £850, Lecturer (Grade II) £900 to £,1300 (bar) to £1,650 The appointment is to be made as soon as possible and the successful candidate will be required to take up duty not later than January 1, 1960

Applications, including the names of two persons to whom reference may be made, should be sent to the Registrar, The University, Bristol, 8, from whom further particulars may be obtained

---

UNIVERSITY OF CANTERBURY
CHRISTCHURCH NEW ZEALAND
ASSISTANT LECTURER IN CHEMISTRY

Applications are invited for the above position The salary attached to the position will be at the rate of £780 per annum, rising by annual increments of £50 to £880 per annum Commencing salary will be in accordance with qualifications and experience An allowance is made towards travelling expenses

Further particulars and information as to the method of application may be obtained from the Secretary, Association of Universities of the British Commonwealth, 36, Gordon Square, London, W C 1 Applications close in New Zealand and London on September 30, 1959

UNIVERSITY OF CANTERBURY
CHRISTCHURCH, NEW ZEALAND
LECTURESHIPS IN CHEMISTRY

Applications are invited for lectureships within the Department of Chemistry There are two vacancies and applicants should have special qualifications or experience in either Inorganic or Organic Chemistry The salary range is £1,025 to £1,275 per annum, rising by annual increments of £50 and the initial salary will depend on qualifications and experience An allowance is made towards travelling expenses

Further particulars and information as to the method of application may be obtained from the Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W C 1 The closing date for the receipt of applications in New Zealand and London is September 30, 1959

UNIVERSITY OF LONDON
READERSHIP IN ORGANIC CHEMISTRY AT BIRKBECK COLLEGE

The Senate invite applications for the Readership in Organic Chemistry tenable at Birkbeck College (salary £1,475 to £1,775 to £2,150 a year plus £80 London Allowance)

Applications (10 copies) must be received not later than September 15, 1959 by the Academic Registrar, University of London, Senate House, W C 1, from whom further particulars may be obtained

---

UNIVERSITY OF BIRMINGHAM
CHAIR OF CHEMICAL ENGINEERING

Applications are invited for the Chair of Chemical Engineering, together with the Headship of the Department of Chemical Engineering This post will be made vacant by the retirement of Professor F H Garner, O B E , on September 30th, 1960

Applications (three copies), with full details of qualifications and experience, together with the names of three referees, should be sent, by October 15th, 1959, to the Registrar, The University, Birmingham, 15, from whom further particulars may be obtained

---

UNIVERSITY OF CANTERBURY
CHRISTCHURCH, NEW ZEALAND
LECTURESHIP IN PHYSICS

Applications are invited for the above position It is hoped to appoint someone who is prepared to work in the field of the solid state, but applications will be considered from persons with experience and interest in other fields The salary will be at the rate of £1,025 per annum, rising by annual increments of £50 to £1,275 per annum Commencing salary will be in accordance with qualifications and experience and an allowance will be made towards travelling expenses

Further particulars and information as to the method of application may be obtained from the Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W C 1 Applications close in New Zealand and London on September 30, 1959

SCIENTIST or scientific technologist required for work on treatment of coke oven effluents and other investigations connected with the carbonisation of coal Qualifications of at least H N C in Chemistry are essential, and preference will be given to those holding a degree or A R I C The successful candidate will work at the Avenue Carbonisation and Chemical Plant of the N C B near Chesterfield It is envisaged that the initial appointment will be at not less than £700 in a scale whose maximum will be fixed according to qualifications The post is superannuable

Please apply, within seven days, giving age and full details of qualifications, experience, and present post to Divisional Chief Staff Officer, National Coal Board, East Midlands Division, Sherwood Lodge, Arnold Nottingham quoting S V 1000

LIVERPOOL RADIUM INSTITUTE MANAGEMENT COMMITTEE

Applications are invited for the post of Physicist (Senior Grade)

Candidates must hold a First or Second Class Honours Degree in Physics, with preferably, some years' experience in Medical Physics

Opportunities for research are available in a wide range of problems

Salary and conditions of service as laid down in P T A Circular No 71 as approved by the Whitley Council

Applications, together with the names of two referees, should be addressed to the Secretary, Liverpool Radium Institute, Management Committee, 1 Myrtle Street, Liverpool, 7, not later than seven days after the appearance of this advertisement

---

GOVERNMENT OF NORTHERN IRELAND
CIVIL SERVICE COMMISSION

Applications are invited for two permanent and pensionable posts of Scientific Officer in the Department of Industrial and Forensic Science, Ministry of Commerce) (1) Biologist with botany as a)principal subject (2) Chemist For this post a knowledge of pharmacy or food and drugs would be an advantage For both posts an appropriate first or second class honours degree or an approved equivalent qualification is required Salary scale £635–£1,120 Entry point will be determined according to the qualification and experience of the successful candidates Preference for ex-Servicemen

Further particulars and application forms obtainable from the Secretary, Civil Service Commission, Stormont, Belfast, should be returned by September 2, 1959

UNIVERSITY OF MALAYA
(SINGAPORE DIVISION)

Applications are invited for (A) Lectureship or (B) Assistant Lectureship in Pharmacology Salary scales For medically qualified candidates (A) £1,295 by £49 to £1,442/£1,540 by £56 to £1988 per annum, (B) £1,148 by £49 to £1,246 per annum For non-medically qualified candidates (A) £1,148 by £49 to £1,442/£1,540 by £56 to £1,820 per annum, (B) £1,001 by £49 to £1,099 per annum, entry point determined by qualifications and experience Allowances expatriation in range £280–£308 per annum, cost of living in range £210–£560 per annum Passages for appointee, wife and children under 12 years Part-furnished quarters at reasponable rent Provident Fund Scheme

Detailed applications (eight copies) naming three referees by September 30, 1959 to Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W C 1, from whom further particulars may be obtained

---

UNIVERSITY OF MELBOURNE
SENIOR LECTURER IN CLINICAL BIOCHEMISTRY

Applications are invited for the above position The Senior Lecturer's duties will be chiefly with medical students and it is essential that he should be familiar with modern methods in clinical biochemistry It is also desirable that he should hold medical qualification

The salary range is £A2,100–£A2,500 per annum or, if medically qualified, £A2,200–£2,800 per annum Commencing salary will be fixed according to qualifications Superannuation similar to F S S U in Great Britain will be provided

It is desirable that the appointee should commence duty early in 1960, and preferably not later than March 1

Conditions of appointment may be obtained from the Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W C 1

Applications close, in Australia and London, on September 15, 1959

UNIVERSITY OF SOUTHAMPTON, Zoology Department Research Assistant required from October 1, 1959 to investigate effects of chemical pollutants on marine organisms Good degree in biological science or physiology and some research experience essential Maximum salary £550 according to qualifications

Applications not later than September 12 to the Registrar, University of Southampton, from whom further particulars can be obtained

---

LAMBETH HOSPITAL
BROOK DRIVE, S E 11

Physicist (Basic Grade) required, with University degree, for routine and development work in Hospital Physics Previous experience not essential Salary scale during probationary period £645 by £25 to £670 by £30 (2) to £730 per annum, plus London Weighting Allowance

Applications stating age, qualifications, experience and names of two referees to the Secretary of the above Hospital

---

NIGERIAN COLLEGE OF ARTS

Applications are invited for a Senior Lecturer or Lecturer in Mathematics

Qualifications Good hons degree and relevant teaching experience

Contract Salary Scales Senior Lecturer Grade I £1,980–£2,178 per annum consolidated, Senior Lecturer Grade II £1,254–£1,584 per annum basic plus inducement addition of £180–£300 per annum for overseas appointeed, Lecturer £690–£1,529 basic plus inducement addition of of £180–£300 per annum for overseas appointees

All plus gratuity at £25 or £37 10s for each completed three months' residential service Appointment would be available in one of the above grades and entry point would be according to qualifications and experience

Pensionable terms may be arranged at appropriately lower salaries, or College will be prepared to take over and maintain employers' contributions to former F S S U policies

Partly furnished quarters at one-twelfth basic salary rental Tours 10–18 months but leave normally taken annually in long vacation Free 1st class passages Children's U K maintenance grant up to £150 per annum and passages assistance

Applications (six copies) giving age, qualifications, experience and names of three referees should be sent to the Council for Overseas Colleges, 12 Lincoln's Inn Fields, London, W C 2, by August 31, 1959

UNIVERSITY COLLEGE OF THE WEST INDIES

Applications are invited for Lectureship in Inorganic Chemistry Salary scale £1,150 by £50 to £1,450 by £75 to £1,900 per annum Entry point determined by qualifications and experience Child allowance F S S U Unfurnished accommodation 5 per cent basic salary Passages paid for up to five persons on appointment, normal termination and study leave (once every three years)

Detailed applications (6 copies) naming 3 referees as soon as possible to Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W C 1 , from whom further particulars may be obtained

APPOINTMENTS VACANT

OPENINGS IN THE U.S.A.

Old established American firm with laboratories in urban and rural areas of the North Eastern U S invites applications from creative

ENGINEERS & PHYSICISTS

with at least three years' experience in any of the following fields
semi-conductors, transistors, microwave valves, receiving valves, video valves, cathode ray valves, power valves, etc

Positions are in the fields of research, design, development and production engineering and are connected with a scientific project of a truly unique nature

Top salaries and liberal employee benefits, pension plan, health insurance, etc The Company will pay relocation expenses of applicants and family Interviews will be held in Europe this summer

Please send detailed resumé of background and experience to

WELTON INTERNATIONAL CORPORATION
Industrial Development Consultants
210 Fifth Avenue, New York 10, N Y

THE THERMAL SYNDICATE LIMITED

requires men or women graduates for research and for the production development of pure refractory oxides and other high-temperature materials

Senior and junior staff appointments are available for

1. Chemical Engineers, particularly with experience of fluidization processes
2. Chemists and Chemical Engineers, to work on (a) silicon chemistry (b) the purification of solids and liquids, and (c) reactions in flames and arcs
3. Refractories Technologists
4. Physicists, Geologists and Mineralogists, interested in one or more of (a) optics, (b) microscopy, (c) X-ray methods, and (d) physical testing

Salaries are commensurate with qualifications and experience but will not be less than £700 per annum Staff bonus, non-contributory superannuation, and life assurance schemes are in operation

Apply to the Research Manager, Thermal Syndicate Limited, P O Box No 6, Wallsend, Northumberland

---

A REACTIVE NETWORK DESIGNER is required Applicants should have had three to five years' experience in the design of filters and reactive networks for wide band carrier telephone systems or in some closely allied field and also an appropriate formal academic training They must be fully conversant with the latest design methods including those applicable to crystal filters and able to take full responsibility for this section of the work of the Development Laboratories, including charge of the small group of men engaged on this work

Please write stating age and giving full details of experience and qualifications quoting reference D/2, to the Personnel Manager, Ericsson Telephones Limited, Beeston, Nottingham

---

BIOCHEMIST OR PHARMACOLOGIST, preferably under 35 and with postgraduate experience in University or Industrial research, to head small experienced team investigating toxicological properties of new agricultural and industrial chemicals, at Chesterford Park Research Station (Fisons Pest Control Limited) Saffron Walden, Essex This post offers excellent chances of interesting and responsible scientific studies, under very good conditions Starting salary of £1 250 upwards depending on experience and qualifications —Applications or requests for further information to Personnel Manager, Fisons Pest Control Limited, Harston, Cambridge (quoting Ref No 1487)

CHEMIST

for G E C Applied Electronics Laboratories, PORTSMOUTH
to take charge of a small group in a laboratory dealing with the application of materials, particularly plastics, to electronic equipment The problems handled by the department are varied and interesting and should provide plenty of scope for a keen man

Housing available for a suitable applicant

Applicants should write in the first instance giving details of qualifications, experience and salary required to the Personnel Officer, G E C Applied Electronics Laboratories, Brown's Lane, Allesley, Coventry

---

ILFORD LIMITED

RESEARCH CHEMISTS

Due to the continuing expansion of their research interests, and to the opening of further new Research Laboratories at Ilford during the Summer of 1959, Ilford Limited wish to engage Graduate Chemists for work on the scientific and technological problems involved in photographic manufacture The work will be concerned with all aspects of the photographic process and cover all fields of chemistry including inorganic, organic, physical and colloid chemistry There are opportunities both for those who wish to work on the basic science of photographic manufacture and for those who prefer to see the results of their work applied directly in production There are good prospects of further advancement both within the Research Laboratories and in other divisions of the Company

Applications should be made to the Research Director Ilford Limited, Ilford, Essex

---

THE BRITISH RUBBER PRODUCERS' RESEARCH Association invite applications from Physicists or Physical Chemists with research experience for a Fellowship tenable at the Research Laboratory for the Physics and Chemistry of Solids at Cambridge University under Dr F P Bowden, C B E F R S The work will be concerned with the application of modern physical techniques, particularly high resolution electron microscopy, to the structure and properties of rubbers The stipend will be determined according to the qualifications and experience of the successful candidate in the range £800 to £1,000 per annum plus superannuation under F S S U Consideration would be given to appointing a less experienced candidate (a fresh honours graduate) to a Research Scholarship of value £600 per annum initially, plus fees with arrangements being made for proceeding to Ph D —Apply to the Director of Research, B R P R A 48-56 Tewin Road, Welwyn Garden City, Herts

---

ATTRACTIVE SENIOR VACANCIES exist for Physicists or Physical Chemists in a Research Laboratory in the following fields (a) semi-conductors including vacuum techniques (b) thin film electrical resistors (c) electrical and magnetic ceramics Starting salaries will be determined according to experience/qualifications within the range of £1,100 to £2,000 per annum G V Planer Ltd , Windmill Road, Sunbury-on-Thames, Middlesex

---

UNILEVER LIMITED

Patents Department

A vacancy exists in the Company's Patents Department in London for a Chemist Physicist or Engineer of degree standard Previous patent experience is desirable, but not essential

The work will cover the very wide range of interests of the Unilever organization and will provide extensive experience in all aspects of British and foreign practice and the opportunity to qualify as a Patent Agent

An attractive salary will be offered commensurate with qualifications and experience

Write to the Head of Patents Department, Unilever Limited, Blackfriars, London, E C 4

ROCHE PRODUCTS LIMITED, WELWYN Garden City require a junior laboratory assistant in their Process Research Laboratory This appointment should appeal to a girl or a boy who has just left or is about to leave school and offers opportunities to those having passed the advanced level of the General Certificate of Education in Chemistry or Physics The work will be of an analytical nature and the successful applicant will be trained in the modern analytical techniques of spectroscopy and chromatography —Replies in the first instance should be made to the Secretary Roche Products Limited, 15 Manchester Square London W 1

ENGLISH CLAYS LOVERING POCHIN & Co Ltd , Cornwall, require an Assistant Ceramic Chemist for work in the St Austell Laboratories —Applications should be made in confidence to the Research Director

---

ENGINEERS are required to work on the development and "engineering" of wide band carrier telephone systems The work is concerned with preparing for production equipment which is in the "bread board" stage and for "engineering", for specific customers' requirements, systems which are already in the production stage

An interest in production, backed by a sound theoretical training, is required and a basically practical outlook is essential

The junior posts would suit young men just completing national service after apprenticeship, or equivalent training, but the senior posts demand some years in an appropriate field

Please write stating age and giving full details of experience and qualifications, quoting reference D/3, to the Personnel Manager, Ericsson Telephones Limited, Beeston, Nottingham

---

PHYSICIST TULLIS, RUSSELL AND CO Ltd , Paper Manufacturers, require a Physicist or Electrical Engineer to undertake development work in dielectrics and allied fields Previous experience of work in similar lines desirable but not essential Salary according to qualifications —Applications, giving details of qualifications and experience to the Secretary, Tullis, Russell and Co Ltd Markinch, Fife, Scotland

---

W & T AVERY, LTD

invite applications to join their team of

DEVELOPMENT ENGINEERS

The ideal applicant would preferably have a good university degree and some industrial experience, fitting him to co-operate on investigations of

NEW ELECTRO-MECHANICAL PRODUCTS

He should also be conversant with techniques employed in

INSTRUMENTATION AND CONTROL

Salary and prospects are attractive and a pension scheme is in operation

Please reply, giving details of age experience and qualifications to Personnel Manager, W & T Avery Limited, Soho Foundry, Birmingham

---

THE DISTILLERS COMPANY LIMITED

SPECTROSCOPIST

The Company wishes to appoint a further spectroscopist to the staff of its Central Research and Development Department Epsom, Surrey , he will apply absorption spectroscopy and mass spectrometry to the solution of problems arising in the preparation and manufacture of chemicals, plastics and antibiotics

Candidates, aged not over 30, should hold a good honours degree, or an equivalent qualification , postgraduate experience of spectroscopic work, either in industry or for a postgraduate degree, would be an advantage

Write
STAFF MANAGER,
THE DISTILLERS COMPANY LIMITED
21 ST JAMES'S SQUARE,
LONDON, S W 1
Quote Ref 60/59 N

BIOCHEMIST

Smith & Nephew Research Ltd invite applications from Biochemists to fill a vacancy in their Biochemical Laboratory The work forms part of an integrated programme in the field of Chemotherapy, including investigations into the metabolism of drugs, and studies on isolated enzyme systems Candidates should possess a First or Second Class Honours Degree in Biochemistry and preferably have one or two years' research experience, but applications from newly qualified graduates will also be considered Salary will be according to age, qualifications and experience The Company's premises are in a country district 25 miles north of London and conditions of employment are well in keeping with recognised levels and include a contributory pension scheme Write giving details of age, qualifications and previous experience to — Research Manager (Administration), Smith & Nephew Research Ltd, Hunsdon Laboratories, Ware, Herts

MIDLAND SILICONES LIMITED requires a GRADUATE CHEMIST aged 28–33 as HEAD of the Textiles and Resins Section in its Product Development Group at Barry, Glam The work is in a rapidly expanding department shortly to move to new laboratories It involves leading a team of chemists engaged on investigations and applied research aimed at developing new and improved Silicone resins and textile treatments Research experience is essential either at University or in industry This post will interest those who have been undertaking research and who now wish to obtain experience of leadership

The Company operates a non-contributory pension scheme and a house purchase scheme is also in operation

Please apply stating briefly age, qualifications and experience to the Staff Officer (Ref No 573), Albright and Wilson (Mfg) Limited (with whom Midland Silicones is associated), P O Box No 3, Oldbury, near Birmingham

CHEMIST OR BIOCHEMIST A vacancy has arisen for a chemist or biochemist in the Medical Radiobiology Department of the Atomic Energy Division Applicants should have some experience in handling biological materials, radioisotope and/or radiochemical experience would be advantageous Age preferably under 35 years Ph D desirable, but not essential Salary in accordance with age and experience Apply Personnel Manager (JDA), The General Electric Company Limited, Erith, Kent

WANTED Technicians for electronic development of test equipment Accommodation available to selected personnel LEC, Bognor Regis

HIGH VOLTAGE RESEARCH

Graduates in electrical engineering or physics or holders of the H N C in Electrical Engineering, are required for experimental research on high voltage problems in a high voltage research laboratory The work covers a wide range and includes the construction and use of impulse voltage and impulse current generators, high direct voltage generators, and electronic equipment

Applicants should be able to carry out investigations without close supervision

Previous works' training and laboratory experience are desirable but not essential

Applications quoting reference N 13 and giving relevant personal details, qualifications and experience should be sent to —

Personnel Manager, Metropolitan-Vickers Electrical Co Ltd, Trafford Park, Manchester, 17

PHYSICIST

The Co-operative Wholesale Society Limited has a vacancy for a qualified physicist of suitable experience in its Technical Research Department Manchester

The successful candidate will be required to work under the direction of the Section Head, on the development of new physical methods and instruments for the quality control and research investigation of a wide variety of products and processes

Facilities include good holidays, canteen, and staff pension scheme Commencing salary according to qualifications and experience

Applications, stating age, education experience and qualifications, should be addressed to the C W S Limited, Central Labour Department, 1 Balloon Street, Manchester 4, endorsed "Physicist—Technical Research Department"

CHEMIST required to work in the Control Laboratory of Arthur Guinness Son & Co (Park Royal) Ltd The essential minimum qualification for this appointment is a First or Second Class Honours Degree with Chemistry as the principal subject This appointment is open to both men and women. The salary paid to the successful candidate will be according to age and experience Four weeks annual leave, five-day week, non-contributory pension scheme Applications should be made in writing to Personnel Manager, Park Royal Brewery, London, N W 10 Ref PL/N

GRADUATE CHEMIST interested in Physics and Chemistry required for research into the behaviour of paper during printing A new field of wor, on photogravure is being started Experience of the printing industry would be an advantage but is not essential Salary in range £650–£1,150 Superannuation Application forms from Secretary, The Printing, Packaging and Allied Trades Research Association, Randalls Road, Leatherhead, Surrey Please quote GC/6/59

LIBRARY ASSISTANT (FEMALE) WITH good knowledge of German required for Metallurgical Library in Slough, Bucks Duties include Abstracting of Technical Articles, Translations, general Library and Information work and Typing —Please apply, giving full details of experience to Box No 803, T G Scott and Son Ltd, 1 Clement's Inn, London, W C 2

IMPERIAL CHEMICAL INDUSTRIES Limited Pharmaceuticals Division, has a vacancy on the established staff of the Alderley Park Research Laboratories in Cheshire for a male or female Laboratory Technician with experience in Histology up to the standard of the Diploma in Pathological Technique of the I M L T, the possession of which would be an advantage Applicants for this appointment should preferably be below the age of thirty —Applications, with full particulars, should be addressed to the Staff Manager Imperial Chemical Industries Limited, Pharmaceuticals Division, Fulshaw Hall Wilmslow, Cheshire

HIGH DUTY ALLOYS LTD, RESEARCH Division, Slough, Bucks Physical Metallurgist or Physicist required for fundamental research on the phenomena associated with fatigue and creep of light alloys Candidates should have an honours degree and preferably some experience of university research, and be under 30 years of age The work will be in a modern and very well equipped laboratory, and encouragement is given for the publication of results A generous salary, depending on qualifications and experience is available, and there is also a Pension Scheme in operation —Please write, giving full details to the Staff Manager, address as above

LARGE CONTINENTAL PHARMACEUTICAL COMPANY requires the services of a well qualified scientist in the medical or pharmacological field to fill an important post in the sphere of international research The holder would be required to travel extensively, maintaining contact with research centres and attending medical congresses in connection with new drug development The successful candidate would live on the continent and a knowledge of the French language would be desirable The situation will be amply remunerated

Curriculum vitae should be sent with applications to Box No 804, T G Scott and Son, Ltd, 1 Clement's Inn, London, W C 2

GRANTS & SCHOLARSHIPS

UNIVERSITY OF LONDON
GRANTS FOR RESEARCH

Applications are invited from members of the University and teachers in Schools of the University for grants from the Central Research Fund to assist specific projects of research and for the provision of special materials and apparatus Grants are not made for normal maintenance Applications must next be received not later than 31st August Forms of application and further particulars may be obtained from the Secretary to the Central Research Funds Committee, University of London, Senate House, London, W C 1

IMPERIAL COLLEGE OF SCIENCE AND TECHNOLOGY
SOLID STATE RESEARCH

A few research bursaries exist for Physicists, Chemists or Metallurgists with good honours degrees for higher degree work on (a) deformation characteristics of ceramics (b) properties of oxide films (c) structure of liquid alloys (d) transmission electron microscopy Minimum value £400 per annum plus fees

Applications to Professor J G Ball, Metallurgy Department, Imperial College, London, S W 7

RESEARCH STUDENTSHIPS
OVERSEAS CIVIL SERVICE
STORED PRODUCTS ENTOMOLOGY

It is proposed to award two Colonial Research Studentships during 1959 to provide training for research into the post-harvest problems of storage of produce in Colonial territories

The award of a studentship carries with it an obligation to work for at least three years in Colonial territories on completion of the training period of about 15 months, if required to do so, and provided a suitable post is available

Tax free maintenance allowances of £420 per annum with allowances not exceeding £145 per annum for wife, £50 first child and £30 each succeeding child are payable during training Subsequent appointment may be to either the Research or Agricultural Branch of the Overseas Civil Service

Candidates, with a good Honours degree in biological subjects, are invited to write to the Director of Recruitment, Colonial Office, London, S W 1, for the necessary application form quoting BCD356/236/01

MISCELLANEOUS

HUMANISM—A MODERN OUTLOOK — Write Ethical Union, 13 Prince of Wales Terrace, W 8

PHYSIOLOGY

An Exteroceptive Block to Pregnancy in the Mouse

EXPERIMENTS on the effect of certain oral progestogens during early pregnancy, in continuation of previous observations[1] on non-pregnant animals, involved placing a recently mated female receiving oral progestogen with a strange male In a number of the mice the procedure resulted in failure of pregnancy from the first mating and a new mating within 3–6 days Control experiments showed that the same effect was produced by dosage with inert material or even without any treatment other than the introduction of a strange male at 24 hr after mating 20 out of 49 females behaved in this way, a far greater proportion than could be attributed to the expected incidence of anovular cycles Only about 8 per cent of young females, as used, return to œstrus within 4–5 days if removed from the male after their first mating, or copulate again at this time if they are left with the male Moreover, among the suspect females there was a failure of the pseudopregnancy which might have been due to poor stud males Experiments were therefore undertaken to explore this effect

Two test situations were devised Situation *A* was as already mentioned, that is, the recently mated female was paired with a strange partner 24 hr after copulation with the stud male Situation *B* was one of proximity without contact, the female being housed in a small cage inside a stock box containing other mice which could climb about the cage but not enter it

The stud males and all the females were albinos The test males were either albino or wild-type Young virgin females were mated in pairs with a stud male , the females were removed from the male when the vaginal plug was found and housed together overnight 24 hr later they were presented with the test situation The females were generally left in the test situation for 7–10 days, and they were then removed to normal mouse boxes The pregnant females were isolated before parturition, and females which became pseudopregnant or in which the pregnancy had been blocked received a fertility test with a stud male The few females which proved to be infertile were excluded Daily vaginal smears were examined

The results of these investigations are briefly summarized in Table 1

Table 1 PREGNANCY BLOCK IN THE MOUSE

The females were separated from stud males on finding vaginal plug, and housed together until presented with the test situation 24 hr later

Test situation	Females having blocked pregnancies	
	Proportion	Per cent
A Housed with		
Strange normal male (albino)	19/69	28
Strange wild-type male	25/35	71
Castrated male (albino)	13/50	26
Another female (parous or ovariectomized)	0/48	—
Original stud male	0/32	—
B Proximity without contact that is, in cage inside stock box containing		
Albino males	8/32	25
Wild-type males	52/68	76
Females	0/49	—

Pregnancy was blocked and implantation inhibited in nearly 30 per cent of females by the introduction of a strange male within 24 hr of coitus , it was so blocked even by the presence of a castrated male Pregnancy was not affected by the return of the female to her original stud male or by the presence of a strange female, whether parous or ovariectomized Contact between the sexes was not necessary for this effect Pregnancy was also blocked when the female was caged inside the male stock box Among parous females, pregnancy was less readily blocked than among non-parous by contact with a strange male, but apparently broke down as easily when the female was housed inside the male stock box This suggests that the latter situation supplies a stronger stimulus

In both test situations the superiority of the wild-type males over the albinos as pregnancy blocking agents was highly significant The reason for this difference is not understood, and as yet male mice of other strains have not been tried Two different strains of females, one albino and the other pink-eyed champagne, were tested in small numbers in situation *B* Both exhibited pregnancy block in similar proportions to those found for the original mice

The use of the genetically marked wild-type test males showed that superfœtation did not occur Of 35 females, 15 mated with the test male All 15 gave birth to black-eyed young only (123 young) This includes one female in which coitus with the test male took place within a few hours of introduction, her litter of 8 black-eyed young being born 19 days later, 20 days after finding the vaginal plug from the stud albino male

No mutual reaction between females as regards pregnancy block was indicated either when the test situation involved other females or when the mated females were themselves placed singly, in pairs, or in threes in the test situation It is well established, however, that females exert a powerful effect upon one another in terms of the œstrous cycle[2] and the incidence of mammary cancer[3], and that the presence of a male tends to synchronize the cycle of non-pregnant females[4]

Further experiments designed to throw light on the mechanism involved in this pregnancy block of exteroceptive origin are in progress The pituitary and the hypothalamus are probably both implicated

Retinal Responses of Pink Salmon associated with its Downstream Migration

THE seaward migration of juvenile Pacific salmon is usually nocturnal and confined to a relatively brief portion of the night[1] It has been suggested that "as the light intensity falls rheotactic responses, which are to a large degree dependent on vision, fail, and these fish pass down stream in shoals The fact that such mass movements occur during a rather precise period of the night is probably due to the dark adaptation of the eye and a period of night blindness"[2] In support of this view, a recent histophysiological examination of the retinæ from several species of *Oncorhynchus* has shown an incompletely dark-adapted condition of the retinæ at the time of most active downstream migration[3,4] As a further test of this hypothesis, the retinæ from fish killed at different light intensities during the evening and early morning have been compared with the retinæ from fish which were completely adapted to the same light intensities in the laboratory The pink salmon fry (*Oncorhynchus gorbuscha*), probably the most specialized of the downstream migrant salmon[1], was selected for the study

Migrant pink salmon were collected from a trap in Jones Creek, British Columbia, and brought into a dark room of the laboratory Groups of five fish were exposed for 90 min to each of seven light intensities, ranging evenly from 10^2 to 10^{-4} ft -candle The period of exposure was sufficient to bring about a complete adaptation[3,4] Fish captured in the same place and in like manner were placed in glass aquaria which were located in an exposed position in the river where the fish had been migrating The bottoms of the aquaria were covered with sand and gravel From these aquaria, fish were sampled at seven times when the incident light intensity reached the same values used in the laboratory This was done both at twilight and at dawn Light intensities of 10^{-1} ft -candle and greater were measured with 'Photovolt' model 200 photometer and light intensities below this value with 'Photovolt' model 520-*M* electronic photometer

The eyes of teleost fish adapt themselves to altered light conditions by pronounced changes in the distribution of the retinal epithelial pigment and the position of the rods and cones When the light intensity falls below threshold values the retinal pigment concentrates and the rods and cones migrate due to the contraction and expansion, respectively, of their myoids These movements are in direct proportion to the logarithm of the light intensity Thus in bright light, the rods are shielded by the pigment and the cones placed directly in the path of light, whereas in low light intensities and darkness, the rods are brought directly in the path of light and the cones migrate closer to the concentrated pigment These processes can be followed by measuring the thickness of the pigment and cone layers The cones are more obviously delimited for this purpose than the rods The histological techniques and methods of measuring retinal changes have been described[3,4] The values presented here are means for 50 measurements made from 10 eyes in each case

Fig 1 shows that both pigment and cone layers of the pink salmon retina are in a semi-adapted state during the periods when the light intensity is rapidly changing in the evening and in the morning The difference between the fully adapted laboratory picture and the semi-adapted state in Nature is less at dawn than in the evening This is in accord with an earlier demonstration that light adaptation is more rapid than dark adaptation in this species[4] Under natural conditions, in the evening, both pigment and cones are in a fully adapted state at intensities above 1 ft -candle However, between this level (the cone threshold) and 10^{-3} ft -candle the retinæ of animals fixed in the field are not as completely adapted as those in the laboratory At 10^{-4} ft -candle adaptation is the same in both groups It requires about 45 min (Fig 1) for the light intensity to fall from 1 to 10^{-4} ft -candle Ali[4] has shown that retinal adaptation commences below 1 ft -candle and requires about 45 min to reach a maximum Thus, the changes in the field are in accord with the laboratory findings With increasing light, retinal changes are evident at intensities above 10^{-2} ft -candle and adaptation is essentially complete at 1 ft -candle The rapidity of light adaptation[4] would seem to account for the small differences found in the fish sampled at dawn Actually, the changes in light intensity in Nature are somewhat more rapid at dawn than at dusk (Fig 1)

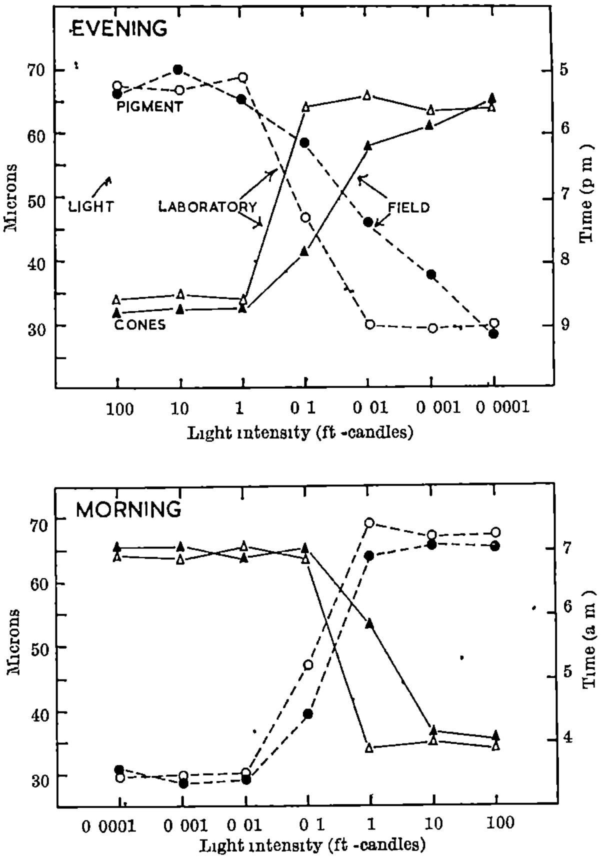

Fig 1 Thicknesses of the pigment and cone layers of pink salmon retinæ when fully adapted to a series of light intensities in the laboratory and at the same intensities under conditions of rapidly changing morning and evening light in the field

These findings are in accord with the theory that migration of pink salmon is initiated when the retina is only partially adapted to the decreasing illumination At Jones Creek, where these observations were made, it was found that 80 per cent of the pink migrants entered the trap between 7 p m and 9 p m (Pacific standard time) on the nights of the study

During this period the light intensity decreased below 1 ft -candle and reached 10^{-4} ft -candle It is not to be expected that all the fish will be affected at the same time since there are shaded and exposed areas in every stream These observations, however, support well the theory that, whether the pink salmon is transported or actively swims downstream[1,5], its nocturnal movement will be initiated when visual contact with its environment is reduced or impaired This will be associated with the rather specialized behaviour of rising to the surface of the water at low light intensities[1]

Deoxyribonucleic Acid Formation in Multiplying HeLa Cells

While studying the behaviour of parasynchronously dividing HeLa cells (Gey), Newton and Wildy[1] have measured the amount of deoxyribonucleic acid as a function of the time-interval between one division and the next Their results suggest that the synthesis of deoxyribonucleic acid occurs during two periods in interphase one soon after and one just before cell division Between these periods, in mid interphase, there exists an interval during which the amount of deoxyribonucleic acid (DNA) in the cell remains approximately constant (Fig 1, curve *a*)

Partial confirmation of this result, using a microspectrophotometric technique, has been obtained in a further series of experiments made with randomly dividing cultures Replicate cultures of HeLa cells were grown on cover-glasses held in 10-ml hard glass screw-capped bottles These were made by introducing into each bottle 1 0 ml Gey's saline containing 20 per cent human serum, 0 5 per cent lactalbumin hydrolysate (Nutritional Biochemicals Inc), 100 units/ml penicillin, 100 mgm /ml streptomycin and 0 002 per cent phenol red in which were suspended 250,000 separated cells After incubating at 37° C for 36 hr the cultures were fixed in methanol, stained by the Feulgen technique and the amount of chromophore per cell was measured for 70 cells (from two different cultures) by the two wave-length technique[2],[3], using the microspectrophotometer made by M L Mendelsohn[4] in the Department of Radiotherapeutics, Cambridge From these measurements a histogram has been constructed which shows the distribution of the chromophore, and hence the relative amounts of deoxyribonucleic acid, among the individual cells of the culture (Fig 2)

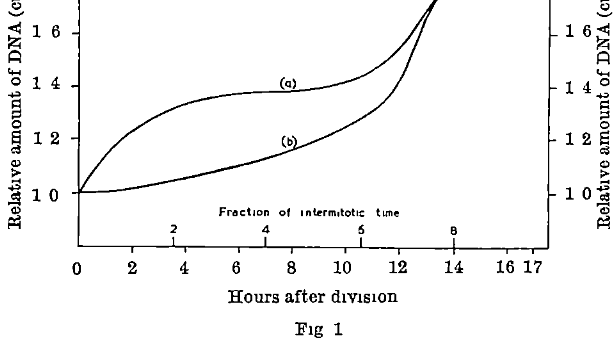

Fig 1

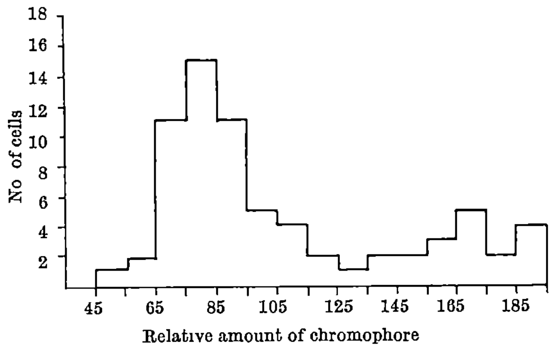

Fig 2

Walker[5] has shown how the synthesis curve for deoxyribonucleic acid may, with certain restrictions, be constructed from such a histogram It is believed that the cultures used for the estimation satisfied these conditions Fig 1, curve *b*, has therefore been constructed from the histogram of Fig 2

Comparing the curves in Fig 1, it will be seen that whereas it is not possible to tell from Fig 1*b* whether the early formation of deoxyribonucleic acid shown in Fig 1, curve *a*, occurs, there is certainly a rapid synthesis beginning about 5 hr before cell division and continuing up to a comparatively short time before cell division

The late period of formation of deoxyribonucleic acid agrees with the findings of Walker and Yates[6] using other kinds of cells and with those of Painter and Drew[7] using tritiated thymidine on cultures of growing HeLa cells

It is, however, difficult to explain the failure to detect the earlier rise in deoxyribonucleic acid which was found with parasynchronously dividing cultures, though the following two explanations should be considered (1) that the present method is inadequate for demonstrating such a rise , (2) that the early rise is characteristic only of parasynchronously dividing cells The latter explanation is thought to be more likely because in such cultures the early rise in deoxyribonucleic acid has never been observed before the first cell division has occurred

A limit to the end of the synthesis period has been obtained by examining autoradiographs of cultures growing in the presence of tritiated thymidine After 36 hr growth, tritiated thymidine (Schwarz 3 0 c /mM) was added to the medium to give a concentration of 1 μc /ml and, 30 min later, the culture was fixed in methanol The cells were afterwards stained with gallocyanin and autoradiographs were prepared In these, although interphase cells were well labelled, examination of several hundred cells in all stages of mitosis showed that none of them was labelled From this it can be deduced that synthesis of deoxyribonucleic acid ends at least 1–1¼ hr before the commencement of mitosis, since the cells were in the thymidine for ½ hr. and the duration of mitosis is about 35 min.

Induction of Parthenocarpy in *Rosa arvensis* Huds. with Gibberellic Acid

As has been previously reported[1], parthenocarpy may be induced in the two non-apomictic species, *R. rugosa* Thunb. and *R. spinosissima* L., by means of α-naphthaleneacetic acid, α-naphthaleneacetamide and 2,4,5-trichlorophenoxyacetic acid. Similar experiments were carried out in an attempt to induce parthenocarpic development in a third non-apomictic species, *R. arvensis*.

The auxin was applied in two ways to the unopened flower-bud, which was emasculated by cutting off the 'disk' (including the head of stigmas) immediately prior to treatment. In early experiments aqueous solutions of the auxins mentioned above and indole-acetic acid were injected into the cavity of the receptacle in concentrations ranging from 2 to 25 p.p.m. In later work the auxin was applied to the cut surface as a lanolin paste in concentrations of 0·025–1·0 per cent. Since *R. arvensis* differs from the other two species in having a much lower ascorbic acid content[2,3], additional mixtures, including ascorbic acid, were used.

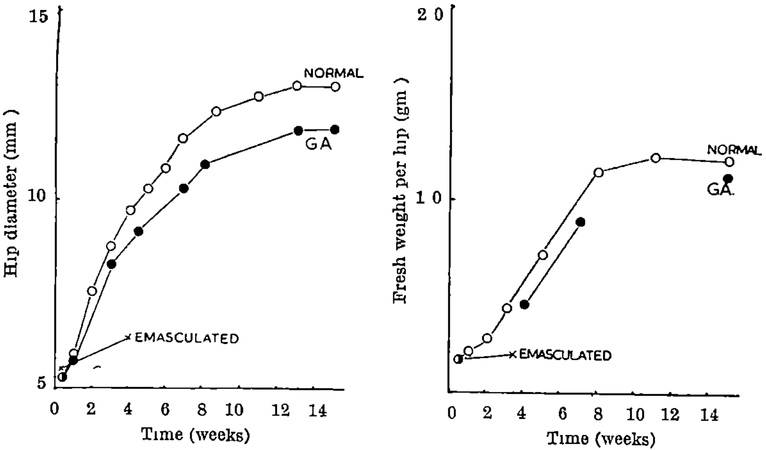

Fig. 1. The growth in terms of average diameter and fresh weight of normal hips, ○—○; emasculated flower-buds ×—×; and emasculated flower-buds treated with 1·0 per cent gibberellic acid in lanolin, ●—●

Almost all these experiments produced negative results, the emasculated control hips usually surviving longer than those treated with auxin. Out of a total of about 300 buds treated, only four showed any signs of growth; these had received the lowest concentration of auxins in lanolin and two of them had had ascorbic acid.

Since the development of rosaceous fruit after fertilization is characterized by increase in cell size rather than in cell number, the properties demonstrated for gibberellic acid suggested that it might be effective in inducing parthenocarpic development. In February 1958 parthenocarpic hips of *R. rugosa* were produced in the greenhouse by the application of gibberellic acid and shortly afterwards similar results were recorded for *R. spinosissima*[1].

In June 1958, 200 flower buds on a bush of *R. arvensis* were emasculated and 1·0 per cent gibberellic acid in lanolin was applied. Control groups of normal and emasculated buds were also selected; it had previously been shown that the application of lanolin alone produced no response. Samples from each group were harvested at intervals for determinations of fresh and dry weight, and Fig. 1 shows the development of the different groups of hips in terms of average hip diameter and fresh weight.

The main period of fruit-drop in *R. arvensis* is 3–5 weeks after flowering; 46 days after treatment with gibberellic acid 107 out of 150 hips were developing parthenocarpically, which represented a fruit-set of 71 per cent compared with 45 per cent for the normal, fertilized hips under these field conditions. None of the emasculated buds developed. Of the 57 parthenocarpic hips allowed to remain until maturity at 14 weeks after treatment, 48 had the appearance of normal, ripe hips while the other nine were smaller and not fully pigmented.

The *Triticum* coleoptile straight-growth test of Luckwill[4,5] showed that normal hips appear to contain two acidic, growth-promoting substances having R_F values of 0·1–0·2 and 0·4–0·5 in *iso*propanol/ammonia/water, and a neutral, growth-promoting substance with an R_F of 0–0·1 which is present in small quantities in the bud and flowering stages but which could not be detected 17 days after flowering, or in subsequent assays. None of these three substances was found in either parthenocarpic hips or emasculated controls, but a neutral growth-substance ($R_F = 0·4–0·6$) was present in the emasculated hips and an apparently identical substance was found in the parthenocarpic hips. A consistent growth-inhibitory effect was present in the tests, predominantly in the acid fraction and centred at R_F 0·8 in all stages of normal, emasculated and parthenocarpic hips.

The relationship between achene development and variations in the amount of growth regulators will be reported elsewhere.

HÆMATOLOGY

Anti-A Hæmagglutinins from a Non-Leguminous Plant—*Hyptis suaveolens* Poit.

Certain plants, chiefly their seeds, contain agglutinins for the erythrocytes of various species. Whereas most plant agglutinins make no individual distinctions among human erythrocytes, some act selectively on one or other of the following blood-group antigens[1]: A, A_1, B, H and N. Except for separable anti-H and anti-B agglutinins from the seed capsule of certain species of *Euonymus*, of the family Celastraceae, all specific seed agglutinins have hitherto been obtained from Leguminosae[1].

An anti-A agglutinin has now been found in the seeds of *Hyptis suaveolens*, Poit, of the genus Labiatiae. The agglutinin works best when a fresh seed extract is tested on a flat tile which is gently and continuously rocked. Although it is not very avid when tested with erythrocytes suspended in isotonic saline solution, it agglutinates A_1 and A_1B cells strongly, A_2 weakly, and fails to agglutinate A_2B cells. Thus *Hyptis suaveolens* seed extract sharply differentiates A_1 and A_1B erythrocytes from those of the weaker sub-groups of A and AB; however, it is not as satisfactory for this purpose as *Dolichos biflorus* seed extract[2], which is far more avid.

The *Hyptis suaveolens* agglutinin acts as strongly at 37° C. or 4° C. as at room temperature. It does not cross-react with B or O cells after 24 hr. at 4° C. or when erythrocytes are suspended in albumin; albumin, however, potentiates the agglutination of A_2 and A_2B cells. Agglutination is inhibited by A-secretor saliva and by AB serum. A full description will be presented elsewhere.

The 'new' agglutinin is of special interest because it is the first seed anti-A (anti-A_1) agglutinin to be found outside the Leguminosae. The current trend is to confine the search for specific seed agglutinins to leguminous plants; wide examination of other plant families might be profitable.

I am grateful to D. S. Das for collecting the seeds and for technical assistance. The seeds were identified by the Botanical Survey of India, Poona.

Interaction of Erythrocytes and Endotoxins

Considerable diversity of opinion exists as to the sensitivity of hæmagglutination tests. The discrepancy in results may to some extent be attributed to technical differences. The factors influencing the reaction, the elution of endotoxin *in vitro* and the uptake by erythrocytes *in vivo* have been examined using a dehydrated endotoxin derived from *S. typhi* (*TO*-901). This powder consisted of 68.5 per cent ash, 7.8 per cent moisture, 1.6 per cent protein, 2.2 per cent lipids and, based on L-rhamnose hydrate as standard, 2.7 per cent rhamnose. If the method of calculation described by Webster *et al.*[1] is adopted the polysaccharide content is 14.3 per cent and the endotoxin approximately 20 per cent. The powder was dissolved in isotonic saline, heated to 56° C. for 30 min. and stored at 4° C. for at least 24 hr. before use. The solution had a slight buffer action, *p*H 7.2. Erythrocytes from healthy rabbits were washed and measured with the hæmatocrit. A volume of 0.2 ml. packed cells was used in most experiments.

Endotoxin was adsorbed on to the washed and measured erythrocytes at 37° C. for 1 hr. The cells were then washed three times in 6–8 volumes of isotonic saline and accurately made up to a 20 per cent suspension. Agglutination was performed on slides, using 0.05 ml. of sensitized erythrocytes and an equal volume of a diluted standard *TO*-serum. The slide was agitated regularly and the test read after exactly 10 min.

The amount of endotoxin adsorbed on erythrocytes was dependent on both the absolute quantity of endotoxin available and on its concentration. The speed of the process was proportional to the concentration of endotoxin and related to the temperature, being five to six times faster at 37° C. than at 4° C.

Erythrocytes coated with very small amounts of endotoxin were inagglutinable in antiserum, whereas those with greater quantities of endotoxin agglutinated readily. This afforded the basis for the determination of an 'erythrocyte-agglutinating unit', defined as the smallest amount of endotoxin, incubated with 2 ml. of 10 per cent erythrocytes for 1 hr. at 37° C., which rendered the cells agglutinable in standard serum diluted 1 in 10. One erythrocyte-agglutinating unit was found to be equivalent to 0.16 mgm. of the dehydrated powder. The quantity of crude endotoxin adsorbed on erythrocytes in these circumstances was 0.12 mgm., thus removing 75 per cent of endotoxin from the supernatant. Assuming the crude powder contains 20 per cent endotoxin it appears that 0.2 ml. of agglutinable packed cells under our experimental conditions must be coated with a minimum of 24 µgm. of endotoxin.

Erythrocytes, initially sensitized with sub-agglutinable quantities of endotoxin, became agglutinable on subsequent exposure to endotoxin provided that the sum of the two doses constituted at least one erythrocyte-agglutinating unit. Thus the erythrocytes appear to bind the adsorbed endotoxin quite firmly.

Assuming that the endotoxin was not removed or rendered undetectable except by fixation to erythrocytes, the reduction in endotoxin content as measured by determination of the erythrocyte-agglutinating unit on the supernatant, will be a direct, quantitative expression of adsorption. Experiments along these lines indicated that erythrocytes were capable of binding at least 200 times the minimum amount required for agglutination under standard conditions; that is to say 0.2 ml. packed cells could adsorb more than 200 × 24 µgm. or 4.8 mgm. of endotoxin as calculated, corresponding to 2.2 per cent of their own weight.

Erythrocytes of the same batch, coated with amounts of endotoxin ranging from 1 to 200 erythrocyte-agglutinating units, gave final agglutination titres against the standard serum ranging from 1 : 10 to 1 : 1,280. Hence, the titre of a given serum will vary according to the quantity of endotoxin adsorbed on to the cells. This may explain, at least partially, the discrepancy and inconsistency in results obtained by hæmagglutination tests; it could be overcome by rigorous standardization for which accurate measurement of endotoxin is essential.

Elution of endotoxin at our experimental conditions (*p*H 7.2–7.3) was minimal. Erythrocytes coated with 1.5 times minimum agglutinating dose of endotoxin were still agglutinable after 12 washings in saline at room temperature. Thus, on the assumption that the stability of an erythrocyte suspension is unaffected by washing, it may be concluded that elution is of a low order. Since this could not be measured in erythrocyte-agglutinating units, a technique for estimating smaller quantities of endotoxin in solution was provided by the construction of a dose-response graph in rabbits. The maximum antibody response, as measured by bacterial agglutination, was directly proportional to doses of crude endotoxin ranging from 0.01 μgm. to 1 mgm. Using the dose-response technique for endotoxin estimation, further studies on elution at room temperature showed that endotoxin was released, but that this did not amount to 1 per cent of the adsorbed endotoxin per equivalent volume of saline. Whether the eluted endotoxin originated from intact or disintegrated erythrocytes has not as yet been established; but it is noteworthy that the washings caused slight hæmolysis.

Sensitized, washed cells inoculated intravenously into non-immune rabbits were highly antigenic. A single injection of a suitably adjusted erythrocyte suspension produced, in 7–10 days, agglutination titres up to 1:100,000. The serum of a rabbit previously immunized by endotoxin produced hæmagglutination *in vitro* against its own sensitized cells. Hæmolysis occurred on the addition of complement. Intravenous inoculation of 20 ml. of 50 per cent suspension of these erythrocytes, which agglutinated *in vitro* with the recipient's serum, boosted the antibody production. The animals failed to produce an acute intravascular episode. Nor was there conclusive evidence of a hæmolytic process as measured by serum bilirubin estimations and Schumm's test. This tolerance of what is a serologically incompatible transfusion is unexplained.

In vivo sensitization in rabbits was demonstrated by intravenous injection of large doses of endotoxin. The animals were bled 4 hr. later and the erythrocytes, washed six times in excess saline, were inoculated intravenously into non-immune rabbits. They responded with a significant antibody production. Which part the adsorption *in vivo* plays in the defence against endotoxins has not as yet been established.

Details of these experiments will be published elsewhere.

BIOCHEMISTRY

Interaction of Sucrose Stearate with Starch

It is generally agreed that changes in the starch component of flour are responsible for the staling of bread[1]. Following a report by Bohn[2] that the sucrose stearates are effective as anti-staling agents, a study was made of the interaction of starch with a commercial sample of sucrose stearate, kindly supplied by F. D. Snell, Inc.

Addition of a sucrose stearate solution to a 1 per cent solution of 'AnalaR' starch in 0.1 per cent sodium chloride resulted in the precipitation of some starch. The maximum amount of precipitate (about 20 per cent of the weight of starch) was obtained with concentrations of sucrose stearate above 0.06 per cent.

Extension of the study to undegraded starches (Table 1) showed that the amount of precipitate depended upon the type of starch. Fractionation of the potato starch into amylose and amylopectin[3] followed by precipitation with excess sucrose stearate showed that most of the amylose but little of the amylopectin was precipitated (see Table 2). Treatment with excess sucrose stearate of an artificial mixture of amylose and amylopectin in the ratio in which they occur in starch gave a figure intermediate between that of the whole starch and that which would be expected on the basis of the separate amylose and amylopectin precipitations. These results indicate that the amylopectin is precipitated more efficiently in the presence of amylose than in its absence.

Table 1. Precipitation of Starches by Sucrose Monostearate

Type of starch	Polysaccharide concentration (per cent)	Sucrose monostearate concentration (per cent)	Precipitate (per cent of polysaccharide)
'AnalaR' starch	1.0	0.1	21.6
Potato starch	1.0	0.1	70.9
Wheat starch	1.0	0.1	92.4
Waxy maize starch	1.0	0.1	13.0

Table 2. Precipitation of Starch Fractions by Sucrose Monostearate

Type of starch fraction	Polysaccharide concentration (per cent)	Sucrose monostearate concentration (per cent)	Precipitate (per cent of polysaccharide)
Potato starch	0.4	0.04	72.7
Potato amylose	0.4	0.04	79.9
Potato amylopectin	0.4	0.04	11.1
20 per cent amylose, 80 per cent amylopectin	0.4	0.04	43.9

Controlled acid hydrolysis of potato starch showed that a high molecular weight was important in determining the amount of precipitate formed with sucrose stearate and it is likely that the low yield of precipitate from 'AnalaR' starch could be attributed to this factor.

A study of the change in diameter of wheat starch granules on heating in aqueous suspension in the presence and absence of sucrose stearate showed that the rate of swelling was reduced in the presence of sucrose stearate. From an examination of the change in turbidity on heating wheat starch suspensions (0.1 per cent), it appeared that in the presence of 0.01 per cent sucrose stearate the gelatinization temperature is raised about 10 deg.

As sucrose stearate is firmly bound by starch, it seemed likely that it would interfere with the starch/iodine reaction. This was shown to be so, and that iodine and sucrose stearate compete for the amylose fraction. There was no evidence for any marked interaction between sucrose stearate and amylopectin by this technique. It is possible that the stearate chain of the sucrose stearate molecule occupies a position down the centre of an amylose helix, in the same way that iodine does[1]

A complete account of this work will be published elsewhere

Influence of X-Rays on the Activity of Carbonic Anhydrase in Erythrocytes and on their Hæmolytic Resistance

Since sickle cell anæmia is possibly related to the activity of carbonic anhydrase[1], it is of interest to find some way of inhibiting the enzyme without altering the resistance of the cell membrane Carbonic anhydrase is very stable[2] but its activity can easily be changed experimentally by adjusting the *p*H and temperature, or by adding sulphonamides or certain inorganic ions All these factors, however, have a marked influence on hæmolysis, whereas erythrocytes seem to be rather resistant to X-rays[3]. We therefore decided to examine whether carbonic anhydrase could be inhibited by a dose of X-rays which would have little or no effect on hæmolysis

For the determination of the enzyme activity we designed an improved Warburg technique[4] This method is based upon measuring the rate of evolution of carbon dioxide when a bicarbonate solution is treated with a buffer and the enzyme We calculated the unimolecular velocity constant of the reaction, which is also used as an index of activity by Mitchell, Pozzani and Fessenden[5] The standard error of our measurements was 12 per cent and for the non-catalysed reaction 4 per cent As a measure of the hæmolytic resistance we used the hæmolytic index this is, in conventional experimental conditions[6], the highest dilution of lysin which produces 100 per cent hæmolysis within 2 hr The standard error of our hæmolytic indices was 2 5 per cent Suspensions of 10^7 cells/cm^3 in physiological saline solution were irradiated in vessels of 2 cm^3, dose 100,000 r, instrument Philips 'Compactix', 210 kV, h v l = 4 mm of aluminium, dose-rate 6,700/min

In non-irradiated blood we found the following carbonic anhydrase activities, calculated per cubic centimetre of full blood ox blood, 1 85 Mitchell units, human blood, 1 4, chicken blood, 1 2 Irradiations of four samples of ox blood, two samples of human blood and two samples of chicken blood had no effect on the activity Repeating this dose after 24 hr yielded no inhibition Solutions of purified enzyme (Schering's 'Cartase', 0 1 per cent), treated in the same way, showed an inactivation of 20 and 50 per cent respectively The fact that these high doses of X-rays do affect erythrocytes in other respects, was shown by their hæmolytic index in our controls this was 13,300 with saponinum album (Merck), after irradiation, the index was increased by 10 per cent and after the second dose of 100,000 r the increase was 17 per cent

Our experiments confirm the great stability of carbonic anhydrase, and indicate that this stability is still greater inside the red blood cell we found no decrease in activity of the carbonic anhydrase of erythrocytes after irradiation with 200,000 r The hæmolytic resistance of the cells was clearly diminished by this dose, so that it is possible that irradiation by X-rays will permit us to modify the structure of the cell-membrane without altering its carbonic anhydrase activity

We wish to thank Prof R Ruyssen for advice and encouragement and Prof Van Vaerenberg, who provided the necessary X-ray equipment

A Method for distinguishing between α- and β-Glycosides by the use of Plant Hæmagglutinins (Lectins)

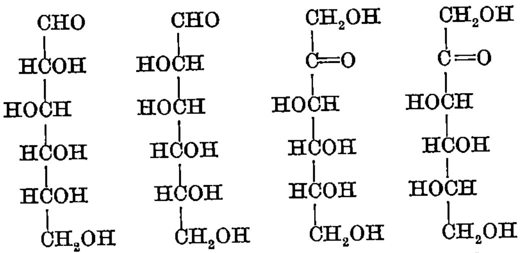
Several plant seeds contain proteins that agglutinate red blood cells[1,2] as do many antibodies For these proteins the name 'lectins' has been suggested[3] They can be as specific as animal antibodies in that they react only with erythrocytes of certain blood groups The ABO blood group specific lectins—as well as the ABO specific antibodies—are inhibited by some simple sugars, mainly components of blood group polysaccharides[1,2,4]. Several 'unspecific' lectins are also inhibited by simple sugars, but these sugars are not necessarily components of blood group polysaccharides[1,2] The explanation of this phenomenon is that the sugars, the structure of which most closely resembles the specific (sugar) group of the red cell receptor, attach themselves to the active site(s) of the lectin molecule, thus blocking them

A monosaccharide as a rule retains its inhibiting power even when linked to other sugars through the hydroxyl group of the first (in ketoses, the second) carbon atom[2,5]. The type of link, whether α or β, seems to be significant In order to throw light on this problem, I made plant agglutinin inhibition tests by a method described in detail elsewhere[6]

The following sugars were used in all experiments D-glucose, D-glucosamine, N-acetylglucosamine, D-glucuronic acid, D-gluconic acid, D-xylose, D-mannose, D-fructose, L-sorbose, D-galactose, D-galactosamine, N-acetyl-D-galactosamine, D-fucose, L-arabinose, D-talose, L-galactose, L-fucose, D-arabinose, D-ribose, D-digitoxose, L-rhamnose, maltose, sucrose, turanose, trehalose, cellobiose, gentiobiose, melibiose, raffinose, and lactose

Seeds of *Pisum sativum* L , *Cytisus sessilifolius* L , *Bandeiraea simplicifolia* Benth , and *Crotalaria juncea* L were used The lectin solutions were prepared by incubating a mixture of seed powder (1 part) and physiological saline (9 parts) for 2 hr at 37° C After centrifugation the supernatant was used 0 05 ml of seed extract containing 2–4 agglutinating doses of lectin and 0 05 ml of sugar solution (pH 7 0) in saline were mixed, and after 30 min incubation at 20° C 0 05 ml of a suspension containing 3 per cent human red cells in saline was added After 2 hr further incubation at 20° C the tubes were read for agglutination The quantitative inhibiting power of the sugars was measured by preparing two-fold serial dilutions of them

The results are shown in Tables 1 and 2 The figures give the final concentration of sugar Of the sugars tested (see above) only those which inhibit either *Pisum sativum* or *Cytisus sessilifolius* lectin at a concentration of 0 08 *M* are included in Table 1 The *Pisum* lectin is strongly inhibited by D-glucose, D-mannose, D-fructose and weakly by L-sorbose The structural differences between the first three sugars are confined to carbon atoms 1 and 2 L-Sorbose differs from D-fructose only with regard to carbon atom 5, but its inhibiting activity is far lower D-Glucuronic acid and D-gluconic acid are not inhibitory



D-Glucose D-Mannose D-Fructose L-Sorbose

It will be seen from the second part of Table 1 that α-glucosides inhibit agglutination by *Pisum* extract as effectively as D-glucose, while β-glucosides are not inhibitory Sucrose is not only an α-glucoside but a β-fructoside as well , however, the fructose part is not probably responsible for the inhibition, since another β-fructoside, raffinose, has no effect on *Pisum* lectin An agglutination by *Cytisus* extract, on the other hand, is inhibited by β-glucosides but not by α-glucosides The failure of glucose itself to inhibit the *Cytisus* lectin is difficult to explain unless it is due to the hexose molecule being too small

Table 1

Sugar		Minimum amount of sugar (m moles/l) inhibiting the action of *Pisum sativum* lectin	Minimum amount of sugar (m moles/l) inhibiting the action of *Cytisus sessilifolius* lectin
	D-Glucose	1 25	>80
	D-Glucosamine	5	>80
	N-Acetyl-D-glucosamine	2 5	>80
	D-Mannose	0 6	>80
	D-Fructose	2 5	>80
	L-Sorbose	40	>80
	(Lactose)	>80	40
α-Glucosides	Maltose	1 25	>80
	Sucrose	2 5	>80
	Turanose	0 6	>80
	Trehalose	0 6	>80
β-Glucosides	Cellobiose	>80	5
	Gentiobiose	>80	40

Table 2

		Minimum amount of sugar (m moles/l) inhibiting the action of *Bandeiraea simplicifolia* lectin	Minimum amount of sugar (m moles/l) inhibiting the action of *Crotalaria juncea* lectin
	D-Galactose	0 6	5
	D-Galactosamine	5	>80
	N-Acetyl-D-galactosamine	0 4	
	D-Fucose	2 5	20
	L-Arabinose	5	20
	D-Talose	20	
	L-Rhamnose	40	>80
α-Galactosides	Melibiose	0 3	5
	Raffinose	0 3	20
β-Galactoside	Lactose	20	1 25

It seems possible, on the basis of the above results, to ascertain the type of the glycosidic link (α or β) of D-glucose, perhaps also of glucosamine, acetyl-glucosamine, D-mannose, in disaccharides and other oligosaccharides the structure of which is only partially known

There are other lectins (*Bandeiraea simplicifolia* and *Crotalaria juncea*) by means of which it seems possible to obtain information of the type of the D-galactosidic (and perhaps D-fucosidic, L-arabinosidic, etc) link, even though the differences between α- and β-galactosides are less definite (Table 2) than differences between α- and β-glucosides (Table 1) Unfortunately the number of galactosides tested is small

If need be, the determinations can be made with 0 01–1 mgm of sugar, and the solution need not be pure , many amino-acids and other sugars, for example, do not interfere There are other methods of studying the nature of the glycosidic link, but the amount of sugar needed for enzymatic or polarimetric studies is greater The information obtained by chromatographic or infra-red spectrographic studies is limited unless an adequate stock of reference compounds is available

Of the seeds quoted above only those of *Bandeiraea simplicifolia* may be difficult to get The rest are obtainable from many seed shops, and can even be replaced by other related species[2] The *Bandeiraea* lectin is blood group B specific—it can be used with B erythrocytes only , and *Cytisus* lectin is O(H) specific—it should be used with O cells The other lectins can be used with red cells of any blood group

The ability of lectins to differentiate between α- and β-glycosides supports J Lederberg's (personal communication) suggestion that there is some connexion between them and plant glycosidases Lectins are not, however, likely to be true glucosidases because (*a*) they are present in ungerminated seeds and their amount does not increase appreciably after germination[7], (*b*) there is no correlation in occurrence between lectins and glycosidases in plant species[8], and (*c*) several purified lectin preparations have been found not to hydrolyse the disaccharides which inhibit agglutination[8]

The monosaccharide specificity of lectins seems to be less definite than that of glycosidases, though glycosidases are not strictly specific , the members of a certain homomorphous sugar series (sugars with an identical pyranose or furanose ring) behave more or less alike as substrates of glycosidases[9], but many lectins are inhibited by members of two homomorphous series These series can differ with regard to the substituents of carbon atom 2 Thus *Pisum* lectin is inhibited by D-glucose and D-mannose, *Bandeiraea* lectin by D-galactose, D-fucose, L-arabinose and D-talose (see above), and *Lotus tetragonolobus* lectin by L-galactose, L-fucose, D-arabinose and 6-deoxy-L-talose[4] The substituents in carbon atoms 3 and 4 seem to be of the greatest importance to the capacity of monosaccharides to inhibit lectins, a view which was expressed six years ago by Morgan and Watkins[4] with regard to *Lotus tetragonolobus* lectin

I wish to thank Mr E R Vaughan, curator, Botanical Garden, University College of Ghana, who kindly sent me several samples of *Bandeiraea simplicifolia* seeds

Reactivity and Interrelationship of Intermediates in the Hydrolysis of *p*-Nitrophenyl Acetate Catalysed by Chymotrypsin

Kinetic studies by Gutfreund and Sturtevant[1] suggest that *p*-nitrophenyl acetate reacts with chymotrypsin rapidly at a *p*H greater than 6 5 to form monoacetyl chymotrypsin (*AC*–I) and that *AC*–I is then deacylated slowly The kinetic observations are consistent with the esterification of a single serine hydroxyl of the enzyme[2] In contrast, spectroscopic studies[3] of the deacylation of monoacetyl chymotrypsin formed at *p*H 5 0 and isolated according to the procedure of Balls and Wood[4], (*AC*–*A*), show that when *AC*–*A* is brought to *p*H 9 0, a rapid increase in absorption at 245 mμ occurs which is followed by slow decay of the absorption peak Since both the absorption peak and its rate of decay appeared characteristic for N-acetyl imidazole, Dixon and Neurath[3] suggested that the deacylation of monoacetyl chymotrypsin proceeds by a rapid intramolecular shift of the acetyl group from a serine oxygen to an imidazole nitrogen of the enzyme (*AC*–II), and that the rate-limiting step of the enzymatic reaction is the base-catalysed hydrolysis of N-acetyl imidazole Recently, however, we have observed[5] that *AC*–I and *AC*–*A* are deacylated at different rates as measured by the liberation of *p*-nitrophenol from *p*-nitrophenyl acetate catalysed by *AC*–I and *AC*–*A*, and that *AC*–I is converted to *AC*–*A* under the conditions used in the isolation procedure[4]

The result of investigations reported below further delineate the differences between *AC*–*A* and *AC*–I, and suggest an interrelationship between *AC*–*A*, *AC*–I and *AC*–II as well as a structure for *AC*–*A* The experiments illustrated in Fig 1 indicate that *AC*–*A* (salt-free α-chymotrypsin, recrystallized three times , gift of the Sigma Chemical Co , St Louis, Missouri) cannot be deacylated via a single intermediate which decomposes with a single rate-constant identical with the rate of decay ($1\ 7 \times 10^{-3}$ sec^{-1})[3] of the 245-mμ absorption peak Curve 1 represents α-chymotrypsin pre-acetylated for 10 min at *p*H 5 0 with 100 equivalents of *p*-nitrophenyl acetate and mixed at zero time with buffer such that the final *p*H was 8 0 Zero-order steady-state liberation of *p*-nitrophenol is observed within 15 sec The rate of deacylation (k_3) of this enzyme (*AC*–I) calculated from the observed rate of liberation of *p*-nitrophenol is $1\ 6 \times 10^{-2}$ sec^{-1} at 15 6° C Curve 2 represents an experiment in which *AC*–*A* was mixed at zero time with *p*-nitrophenyl acetate at *p*H 8 0 The rate of liberation of *p*-nitrophenol during the first 30 sec is only about 70 per cent of the rate observed in curve 1 (*AC*–I), and essentially the same as *AC*–I after 300 sec The deviation from zero-order kinetics observed during the first 300 sec of the reaction of *AC*–*A* with *p*-nitrophenyl acetate is interpreted as indicative of the rates of reactions involved in the conversion of *AC*–*A* to *AC*–I These reactions are presumably the deacylation of *AC*–*A* and its reacylation at *p*H 8 0 to form *AC*–I However, the rate of conversion of *AC*–*A* to *AC*–I is incompatible with the complete deacylation of *AC*–*A* via the N-acetyl imidazole intermediate (*AC*–II), as can be seen

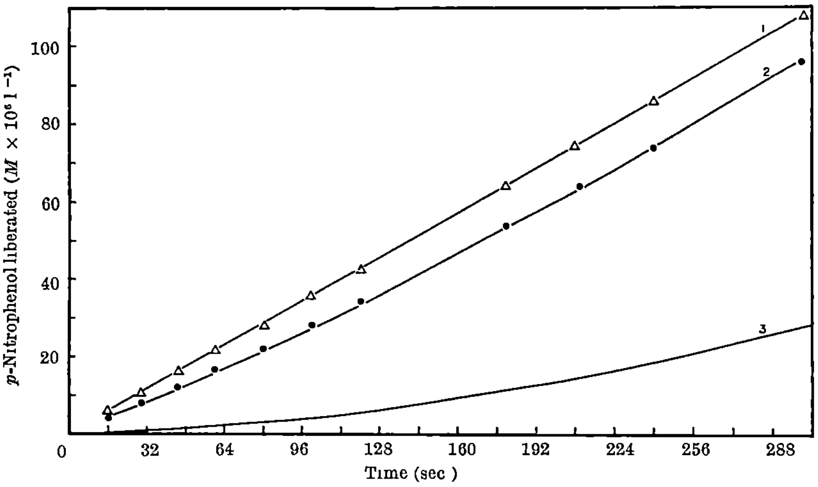

Fig 1 The liberation of *p*-nitrophenol in the catalytic hydrolysis of *p*-nitrophenyl acetate by α-chymotrypsin and monoacetyl-α-chymotrypsin preparations at 15 6° C in *tris*-(hydroxymethyl)-aminomethane–maleate buffer, *p*H 8 0 Total ionic strength 0 12 *M* , $[E]_0 = 2\ 1 \times 10^{-5}\ M$ $[S]_0 = 1\ 7 \times 10^{-3}\ M$ Curve 1, chymotrypsin preacetylated for 10 min with 100 equivalents of *p*-nitrophenyl acetate at *p*H 5 0 and 15 6° C and then mixed with buffer at zero time to bring the *p*H to 8 0 , curve 2, isolated monoacetyl-α-chymotrypsin (ref 4) (*AC*-*A*) , curve 3, a calculated curve for the catalysis of *p*-nitrophenyl acetate by a monoacetyl enzyme which is deacylated with a rate of $1\ 7 \times 10^{-3}$ sec^{-1}

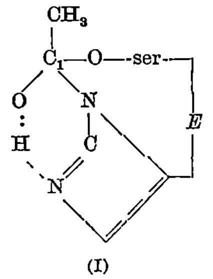
from curve 3 Curve 3 was calculated for a monoacetyl enzyme which is deacylated at a rate characteristic for N-acetyl imidazole ($k = 1\ 7 \times 10^{-3}$ sec $^{-1}$ at *p*H 8 0) Since curves 2 and 3 are not identical one must assume from the spectroscopic studies that the deacylation reaction of *AC–A* can proceed via *AC*–II only partially if at all The rate between the first 15 and 30 sec of reaction in curve 2 is about 70 per cent of the final rate, in curve 3 only about 2 per cent of the final rate It appears, therefore, that only about 30 per cent of *AC–A* can be deacylated via *AC*–II This is consistent with the observation that the absorption at 245 mμ accompanying the deacylation of *AC–A* corresponds to only about 0 4 mole of N-acetyl-imidazole per mole of acetyl-enzyme

The kinetic results appear consistent with two alternatives *AC–A* is either an equilibrium mixture of 70 per cent *AC*–I and 30 per cent of a form of monoacetyl-enzyme which is deacylated via *AC*–II or *AC–A* is a single intermediate which under the conditions used for hydrolysis of *p*-nitrophenyl acetate gives rise to the two separate intermediates, *AC*–I and *AC*–II

To test which of these alternatives is correct, *AC*–I and *AC–A* were allowed to react with hydroxylamine[4] at *p*H 5 5 When the reaction was carried out in water both *AC*–I and *AC–A* reacted to form approximately 1 mole of hydroxamate per mole of enzyme After both preparations were denatured for 2 min in 8 *M* urea at *p*H 5 5 and 23° C the acetyl group of *AC*–I was completely unreactive toward hydroxylamine while that of *AC–A* was completely reactive Since all the acetyl groups of *AC–A* were capable of forming an hydroxamate under conditions which abolish the activity of *AC*–I, then it follows that none of the acetyl groups in *AC–A* are present in the same form as they are in *AC*–I The activity of *AC–A* toward hydroxylamine can be destroyed by denaturing for 10 min at *p*H 5 5 and 23° C or for 2 min at *p*H 3 0 and 23° C These facts are taken into account in proposing the structure for the active site of *AC–A*



(I)

The active site of *AC–A* would be expected to react with hydroxylamine at *p*H 5 5 The results shown in Fig 2 indicate that both *AC*–I and *AC–A* are denatured at the same rate by 8 *M* urea as judged by optical rotation studies Since the active site of *AC–A* is stabilized, not only by the total configuration of the molecule but also by a covalent and a hydrogen bond, it would be more resistant to treatment with urea Removal of the hydrogen bond by urea forms an anionic intermediate which, at *p*H 5 5, leads to the formation of the *O*-acetyl derivative (*AC*–I), which is unreactive toward hydroxylamine in urea solution At *p*H 3 0, the rate of denaturation is faster than at *p*H 5 5 as shown in Fig 2, explaining why the reactivity of *AC–A* toward hydroxylamine is abolished after 2 min in 8 *M* urea at *p*H 3 0 Under basic conditions, such as those used for the kinetic experiments, *AC–A* would be expected to form both the *O*- and the *N*-acetyl derivatives *AC*–I and *AC*–II, by nucleophilic attack at C$_1$

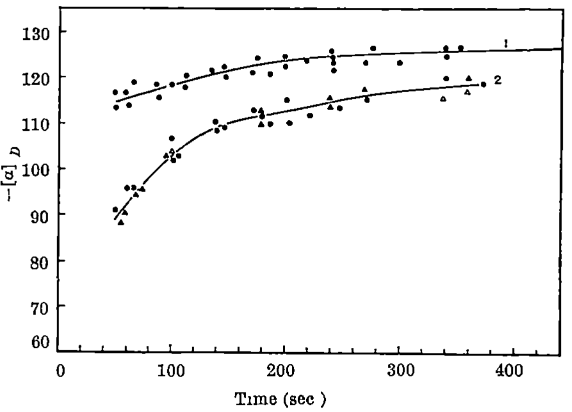


Fig 2 Change with time of the specific rotation of α-chymotrypsin (*CT*) and isolated monoacetyl-α-chymotrypsin (ref 4) (*AC-A* △-△) in 8 *M* urea at 23° C in 0 05 *M* *tris*-(hydroxymethyl)-aminomethane–maleate buffer at *p*H 5 5 (curve 2), and in 0 05 *M* sodium citrate buffer at *p*H 3 0 (curve 1) Optical rotation was measured in a Rudolph photoelectric spectro-polarimeter

The proposed active site of *AC–A* explains the spectroscopic and kinetic results as well as the reactivity toward hydroxylamine

AC–I is kinetically identical to the normal acetyl-enzyme at *p*H 7 0–9 0 Since no significant change in absorption at 245 mμ accompanies the hydrolysis of *AC*–I[5b], there is no evidence for *N*-acetyl-imidazole as intermediate in the normal catalytic reaction

This investigation was supported by grants from the U S Public Health Service and the National Science Foundation We are indebted to Dr Lyman C Craig, Rockefeller Institute, New York City, for the use of the Rudolph photoelectric spectro-polarimeter

Effect of Purine and Pyrimidine Analogues on Reversion of a Tryptophan-requiring Strain of *Escherichia coli*

WE suggested recently that nucleic acid precursors, altered *in vivo* by ultra-violet light, are involved as chemical intermediates in the induction of mutation[1] We have since reported that, in the absence of an adequate source of nitrogen, an immediate and rapid decline in the frequency of mutations induced by ultra-violet light occurs ('mutation frequency decline')[2] We demonstrated that the prevention of this decline depends on the availability immediately following exposure to radiation of a supply of amino-acids, and suggested that the amino-acids are involved in a process of temporary 'stabilization' of the 'potential mutation' (the modified purine or pyrimidine) in the cell prior to its effect in the induction of mutation ('mutation stabilization')[2]. The potential mutation is ultimately 'fixed' into the cell and is no longer subject to those conditions which previously resulted in decline in mutation frequency ('mutation fixation')[2]. Recently we have reported that the progression of 'mutation fixation' is closely correlated with the synthesis of ribonucleic acid in the culture, and suggested that the initial mutagenic event involves the incorporation of the modified nucleic acid precursor into ribonucleic acid[3]. We wish to report here experiments which determine the effect of certain purine and pyrimidine analogues on reversion induced by ultra-violet light in an auxotrophic strain of *Escherichia coli*.

The mutations studied result in reversion to the prototrophic state of *E. coli* strain *WP2* (tryptophan-requiring strain of Witkin)[2]. The basic procedure followed for culture growth, synchronization, radiation exposure, culture treatment, plating and mutation assay have already been described[1,2]. The procedures used for the determination of nucleic acid and protein have also been described[3].

30 purine or pyrimidine analogues were tested by addition (5 mgm./100 ml.) to incubating cultures immediately following exposure to radiation. The substances tested were 5-bromouracil, thiouracil, 5-methylorotic acid, 5-thioguanine, 8-aza xanthine, 6-aza uracil, caffeine, 5-nitrouracil, 6-aza thymine, 8-aza guanine, 8-aza hypoxanthine, 8-aza adenine, 6-methylthiouracil, 5-aminouracil, 5,6 dichloro-1-(β-D-ribofuranosyl) benzimidazole, 5-bromodeoxyuridine, 5-hydroxyuridine, 5-methylthiouracil, 8-aza xanthine, uramil, diazouracil, 6-mercaptopurine, dithiouracil, 5-nitrouracil, 2-amino-4-methyl pyrimidine and 5-bromouridine. The effect of each on mutation response was determined by plating the cells on the mutation assay agar after 60 or 80 min. incubation with the analogue. Of these analogues, 6-mercaptopurine, 5-hydroxyuridine and 6-aza uracil were found to have a marked effect on the mutation frequency response while 6-thioguanine and 5-nitrouracil lowered the mutation response slightly. Preliminary studies with 5-hydroxyuridine have been reported elsewhere[3].

The decline in mutation frequency promoted by 5-hydroxyuridine is initiated after a lag of some 20 min. and is complete after incubation for 60 min. (Table 1). The initiation of the decline in mutation frequency in the presence of 5-hydroxyuridine is correlated with the initiation of synthesis of ribonucleic acid and is complete at about the time the relative amount of ribonucleic acid has doubled. Protein synthesis begins only after a considerable degree of decline in mutation frequency has occurred. Furthermore, synthesis of deoxyribonucleic acid is initiated after the decline promoted by 5-hydroxyuridine is complete. Thus the decline in mutation frequency in the presence of this analogue can be correlated with the synthesis of ribonucleic acid in the presence of the analogue. A plausible hypothesis to account for this fact is that the analogue is incorporated into ribonucleic acid, thus producing 'non-functional' ribonucleic acid and using up the mutagenic substrate. Preliminary studies indicate that 6-mercaptopurine may exert its effect through a similar mechanism.

Table 1. THE EFFECT OF 5-HYDROXYURIDINE ON MACROMOLECULAR SYNTHESIS AND THE YIELD OF ULTRA-VIOLET-INDUCED PROTOTROPHS FROM *Escherichia coli* STRAIN *WP2*

Post-irradiation incubation time† (min.)	5-Hydroxyuridine, 5 mgm./100 ml.*			
	Prototrophs per 10^8 survivors	Relative concentration

30	4,104	1.2	1.0	1.0
40	3,060	1.4	1.0	1.0
60	1,180	1.9	1.5	1.0
80	932	2.4	1.8	1.3

RNA, Ribonucleic acid; DNA, deoxyribonucleic acid.

* Incubation with 5-hydroxyuridine had no effect on survival. The incubation medium was minimal medium (ref. 1) plus casein hydrolysate, 2 mgm./ml. and DL-tryptophan, 0.2 mgm./ml. Ultra-violet exposure was 960 ergs/mm.^{2}

† Incubation prior to plating on to the mutation assay agar (see Doudney and Haas, ref. 3).

Table 2. COMPARISON OF THE EFFECTS OF 6-AZA URACIL AND CHLORAMPHENICOL ON THE YIELD OF ULTRA-VIOLET INDUCED PROTOTROPHS FROM *Escherichia coli* STRAIN *WP2*

Post-irradiation incubation time† (min.)	Chloramphenicol (20 μgm./ml.)	6-aza uracil (5 mgm./100 ml.)*	
	Prototrophs per 10^8 survivors	Prototrophs per 10^8 survivors	Relative ribonucleic acid concentration
0	5,084	5,084	1.0
10	2,480	2,682	1.0
20	1,628	1,850	1.0
30	852	950	1.0
60	820	990	1.1

* Incubation with 6-aza uracil had no effect on survival. The incubation medium was minimal medium (ref. 1) plus casein hydrolysate, 2 mgm./ml., and DL-tryptophan, 0.2 mgm./ml. Ultra-violet exposure was 960 ergs/mm.^{2}

† Incubation prior to plating on to the mutation assay agar (see Doudney and Haas, ref. 3).

We have demonstrated a rapid decline in mutation frequency following addition of chloramphenicol to the culture which is complete to a basal level within 20 min.[3]. Table 2 demonstrates that the decline promoted by 6-aza uracil (unlike that promoted by 5-hydroxyuridine) is closely correlated with the decline promoted by chloramphenicol. 6-Aza uracil, like chloramphenicol, blocks protein synthesis. However, unlike chloramphenicol, the analogue presumably blocks protein synthesis through direct blockage of the synthesis of ribonucleic acid. Uridine will reserve the blockage to ribonucleic acid and protein synthesis and will also prevent the decline in mutation frequency promoted by the compound. We thus assume that 6-aza uracil has the capacity to promote 'mutation frequency decline' as does chloramphenicol by interfering with 'mutation stabilization'.

These studies were supported in part by research grant *C*-3323 from the U.S. National Institutes of Health and by U.S. Atomic Energy Commission Contract *AT*-(40-1)-2139.

Activation of Staphylococcal-free Coagulase by Purified Human Prothrombin

Free coagulase[1] is an extracellular protein produced by pathogenic staphylococci[2], which reacts with coagulase activator[3], present in the plasma of certain animal species, to yield an active material capable of clotting any fibrinogen[1] The active material has been called activated coagulase[4] and has been shown recently, by a study of the kinetics of the reaction between purified free coagulase[5] and an impure preparation of coagulase activator, to be produced during the enzymic degradation of the former by the latter This work, however, shed no light on the vexed problem of the nature of coagulase activator[3,6–9], owing to the inhomogeneity of the coagulase activator preparation employed

Through the kindness of Dr F Duckert of the Medizinische Universitatsklinik, Zurich, we have been able to repeat some of these experiments, using, as the source of coagulase activator, a highly purified sample of human prothrombin prepared by chromatography on barium sulphate and 'Hyflosupercel' by a slight modification of the method used by Duckert, Koller and Matter[10] This material contained about 1,000 units of prothrombin and 160 units of coagulase activator per mgm protein, and was thus enriched between 600 and 700 times (Dr Duckert, private communication)

Solutions of prothrombin in phosphate buffer (0 07 *M* disodium hydrogen phosphate–potassium dihydrogen phosphate, *p*H 6 8) were incubated at 37° C with various concentrations of free coagulase and activated coagulase was assayed in the mixtures as already described[4] The results, which are summarized in Table 1, are essentially similar to those obtained previously[4] and demonstrate the instability of activated coagulase under these conditions The concentration of activated coagulase produced and the length of time before its exhaustion are directly dependent upon the initial concentration of free coagulase in the mixture These facts, together with the finding that the exhausted mixtures still contain coagulase activator but no free coagulase, confirm that free coagulase is enzymically degraded by coagulase activator

Table 1 Formation and Destruction of Activated Coagulase in Mixtures containing a Constant Amount of Purified Human Prothrombin and Various Amounts of Free Coagulase

Values given are for the concentration of activated coagulase (units/ml)

Incubation time of mixture at 37° C (hr)	Concentration of coagulase (units/ml) added to an equal volume of purified human prothrombin (250 μgm /ml)			
	25	10	5	2
0	3 3	1 9	1 2	0 5
1	4 3	2 8	1 4	0 6
2	4 0	2 8	1 4	0 6
3	4 0	2 4	1 4	0 5
4	3 8	2 4	0 9	0 3
5	4 3	1 5	0 8	0 25
6	4 0	1 4	0 6	0 23
8	3 0	0 8	0 5	0 17
22	1 5	0 9	0 34	0 08

After incubation for 22 hr the mixtures were divided into three portions and to (*a*) was added an equal volume of prothrombin 190 μgm /ml , to (*b*) an equal volume of coagulase 25 units/ml and to (*c*) an equal volume of buffer They were then incubated for 10 min and the activated coagulase content measured as before

a	0 5	0 12	<0 1	<0 1
b	3 1	2 7	2 0	2 0
c	0 5	0 13	<0 1	<0 1

In view of the highly purified nature of the human prothrombin used as a source of coagulase activator, it seems likely that the two are identical This suggestion is supported by the observation that the ratio of prothrombin to coagulase activator in normal human plasma is identical with that in the present highly purified preparation of prothrombin

CHEMISTRY

Separation of Polyvinyl Chloride and Polyvinyl Acetate by Chromatographic Methods

The material used in this work was known to contain at least two co-polymers A method of separation was sought which would not require a complex chemical procedure The separation of high polymers by chromatographic means was carried out by Claesson[1], while separations on columns packed with carbon black were attempted by Landler[2]

It was found that absorption decreased with increased molecular weight A column of activated charcoal was packed and saturated with methyl *iso*-butyl ketone The mixture containing the two co-polymers in this solvent was added to the top of the column and washed with the solvent After a few minutes, the elutant was giving a positive test for chloride After 1 hr washing the fractions began to give positive acetate results

In order to attempt some form of confirmation, a method of separation was devised by paper chromatography

The mixed co-polymers in solution were spotted on to a strip of Whatman's No 4 filter paper and air-dried This strip was then allowed to run at room temperature for 45 min , using once again methyl *iso*-butyl ketone as a solvent The strip was then air-dried and sprayed with a solution of one part B D H Universal indicator and one part distilled water The whole strip was then washed in distilled water and dried The acetate spot remained stationary, while the chloride moved with the solvent front R_F values were for chloride 0 985 and 0 0 for the acetate Both spots were eluted, yielding positive tests for acetate and chloride, respectively

To determine the accuracy of the separation, two pure polymers of acetate and chloride were mixed in the solvent These were then spotted on to a No 4 filter paper and run as a control Identical results were obtained as with the mixed co-polymers

This method is not suggested as an analytical procedure but as a rapid means of separating mixed polymers

Further details of this work will be published elsewhere.

A New Method for working up Processing Mixtures containing Anhydrous Aluminium Chloride

ON working up the mixture in order to isolate the products of reactions catalysed by anhydrous aluminium chloride, the first step is usually decomposition with an ice-acid mixture[1]. However, difficulties are often encountered in the separation of the aqueous phase containing the aluminium salts, due to the formation of stable emulsions. This makes the repeated washing of the organic phase necessary to ensure complete extraction of the aluminium salts, a rather tedious operation.

In our experiments we found that a solution of sodium fluoride could be used with advantage at this stage, and also to eliminate interference during later stages. The favourable effect is due to the formation of the complex Na_3AlF_6 which is soluble in water. The advantages of the method may be summarized as follows.

1. The aqueous solution, when it contains sodium aluminium fluoride, is readily and quickly separable from the organic phase, in our experiments, nitrobenzene.

2. When the second step of working up the reaction mixture is steam distillation of an alkaline solution, no separation of the aqueous phase is necessary. Further, as the aqueous phase is already alkaline, no addition of alkali is required to secure the alkaline reaction of the medium.

3. When a neutral solution is wanted during processing, a slightly acidified solution of sodium fluoride can be used. The exact amount of hydrochloric acid necessary can be determined by blank tests on a solution of anhydrous aluminium chloride at the same concentration as the reaction mixture. These blanks are of great importance as the quantity of acid required depends on the quality of the sodium fluoride.

4. Since the method facilitates the working up and analysis of very small quantities, it is particularly suitable for micropreparation and kinetic studies. Although stoichiometrically 6 moles of sodium fluoride are required for each mole of aluminium chloride, we find it best to use at least 7 moles of the reagent.

As an example, part of an unpublished kinetic study will be given here, where a quantitative determination of the ketone was carried out on the mixture obtained by the Fries rearrangement of thymyl acetate in nitrobenzene, in the presence of aluminium chloride.

Preparation of thymyl-methyl ketone. 2·4031 gm. (12·4 m.moles) of 99·14 per cent thymyl acetate was treated with a solution of 4·17 gm. (31·3 m.moles) of anhydrous aluminium chloride (B.D.H.) in nitrobenzene, and the mixture was made up to 20 ml. with nitrobenzene. The mixture was allowed to stand for 5 hr. in a thermostat of 40° C., and then an aliquot of 2 ml. was transferred by pipette into an equal volume of ethanol. This mixture was refluxed for 30 min. with 30 ml. of a solution of sodium fluoride (containing 35 gm. sodium fluoride), 3 ml. of 1 *N* sodium hydroxide and 24 ml. of ethanol. After cooling, the solution was made up at room temperature to 100 ml. with water and allowed to stand overnight in a glass cylinder, 2·5 cm. in diameter, when nitrobenzene separated. A portion of 50 ml. was withdrawn from the clear supernatant with a pipette, treated with 3 ml. of 1 *N* hydrochloric acid and distilled until the temperature of vapour reached 98° C. (approximately 5 min.). The residue was allowed to stand for 2 hr. in an ice box, then the precipitated crystals were filtered through a glass filter, dried at 110° C. for an hour and weighed together with the filter. Thymyl-methyl ketone was then separated from inorganic contaminants by treating the filter with 3 × 5 ml. of hot ethanol. After drying the filter for 20 min. at 110° C., it was again weighed. The difference was 0·0881 gm. The almost white, crystalline product obtained by evaporating the ethanolic solution had a melting point of 122·5–125° C. For $C_{12}H_{16}O_2$, molecular weight 192·25: calculated (per cent): C, 74·97; H, 8·39; found (per cent): C, 74·95; H, 8·07.

The ketone obtained by the classical Rosenmund method[2] was nearly black, m.p. 115–122° C.

The correction for the solubility of the ketone gives a gross yield of 0·092 gm.; thus by the Fries rearrangement a yield of 94·6 per cent was obtained. With suitable modifications the quantity of unconverted ester can also be determined by titration[3].

We wish to thank the Hungarian Academy of Sciences for a grant and the Microanalytical Laboratory of the Institute of Organic Chemistry of the University of Szeged for carrying out the microanalyses.

PHYSICAL SCIENCES

Calculation of a 'Cosmic Ray Age' for the Iron Meteorite 'Carbo'

THE potassium of the iron meteorite 'Carbo', compared with ordinary potassium, is substantially enriched in the isotopes potassium-40 and -41, as shown in the recent isotopic analysis by Voshage and Hintenberger[1]. At least 15 per cent of these isotopes in their sample of 'Carbo' appear to have been produced through the action of cosmic rays. Stoenner and Zähringer[2] found that the concentration of potassium may vary considerably within an iron meteorite. Their analyses were based on the detection of potassium-41 and the assumption that the potassium had the same isotopic composition as terrestrial potassium. If, however, their value of 0·031 p.p.m.

of potassium from one sample is typical of 'Carbo' and is corrected to 0.012 p.p.m. in order to fit the new isotopic analysis, the potassium produced by spallation is at least 4.6×10^{-11} mole/gm. The total ion beam in the Voshage and Hintenberger analysis indicated that the concentration of potassium-40 alone is even greater than 1.8×10^{-12} mole/gm. The amount of potassium produced by spallation is probably about 10^{-11} mole/gm. This figure is quite compatible with that of 1.1×10^{-10} mole/gm. for the helium-3 content[2] because the cross-section for the formation of potassium, including the contribution from argon-39 and calcium-41, seems to be[3] about 40 mb., and the measured cross-section for the production of helium-3 (with hydrogen-3) by means of 3 BeV. protons on iron is approximately[4] 340 mb. The neon also formed by spallation has a concentration[5] of 5.8×10^{-12} mole/gm., which is comparable with that indicated for the potassium.

Radioactive species formed by spallation have been used to estimate the production rate of stable isotopes by cosmic rays. Radiation ages have been calculated in this way for meteorites from their helium-3 and argon-38 contents[6]. The combination of stable isotopes of potassium with the relatively long-lived potassium-40 may also be used to calculate a 'cosmic ray age', Δt in the following equation:

$$\frac{1 - e^{-\lambda \Delta t}}{\Delta t} = \frac{\lambda K_m^{40} (\sigma_{39} - R\sigma_{41})}{\sigma_{40}(K_m^{39} - RK_m^{41})}$$

The relative abundances of the potassium isotopes used are $K_m^{39} = 0.795$, $K_m^{40} = 0.048$, and $K_m^{41} = 0.157$, as reported by Voshage and Hintenberger[1] for the meteorite 'Carbo'. The total decay constant, λ, is taken as 0.529×10^{-9} yr.$^{-1}$. R is the ratio of K^{39}/K^{40} in ordinary potassium.

In addition to the usual assumption regarding a constant cosmic ray flux, some knowledge of the cross-sections for the formation of the potassium isotopes is required. The cross-section versus mass curves for argon formed by high-energy protons on iron and copper are well defined experimentally (refs. 3 and 4 and Bieri, R. H., personal communication). The curves are similar and are skewed towards the side of the neutron-rich isotopes. The known isotopes of potassium suggest that the spallation curve of this element is similarly asymmetrical and that the production cross-sections for potassium-40 and -41 are rather large and approximately the same.

Barr[3] has estimated the approximate production cross-sections for the isotopes potassium-39, -40 and -41 for 5.7 BeV. protons on copper. These cross-sections are 5.2, 9.4 and 9.2 mb., respectively. He inferred them from his measurements of the yields of more than fifty radioactive isotopes produced by the spallation of copper. The observed cross-sections for potassium-42 and -43 were 5.4 and 1.1 mb., respectively. Other spallation products such as argon-39 and calcium-41 contribute significantly to the formation of potassium. The cross-sections for the formation of potassium estimated from Barr's work then become $\sigma_{29} = 14.8$, $\sigma_{40} = 9.4$, and $\sigma_{41} = 14.7$ mb.

The radiation age calculated from the preceding values is $0.6_9 \times 10^9$ yr. It is obvious in the above equation that the value for σ_{39} is comparatively insignificant. This figure may be incorrect by a factor of 2 without influencing the value of the right side of the equation by more than 10 per cent. The relative values for σ_{40} and σ_{41} are important. A difference of even 20 per cent in their ratio affects the radiation age by 1×10^9 years. This seems to be approximately the uncertainty in this radiation age of 'Carbo'; but the relative ages of iron meteorites may be determined with much greater precision. For the radiation age from the potassium to be 4.6×10^9 years, or the same as the lead–lead age[7,8] and the rubidium–strontium age[9,10] of stone meteorites, σ_{41} would have to be about one-half the value for σ_{40}. It should be noted that contamination will have a negligible effect on the radiation age as long as the observed abundance of potassium-40 is much greater than the potassium-40 in ordinary potassium.

The cosmic ray age calculated here for 'Carbo' is essentially the same as its estimated cosmic ray helium age of 0.85×10^9 years[11]. The potassium–argon ages of several stone meteorites are also quite similar. The chondrites 'Kunashak' (grey variety) and 'Pervomaiskii Poselok' (grey variety) have ages of 0.70×10^9 and 0.64×10^9 years, respectively[12]. The two shergotites 'Padvarninka' and 'Shergotty' have ages of 1.0×10^9 years[12] and 0.56×10^9 years[13], respectively. It seems that the stone meteorites belong to two groups, one with radiogenic helium ages of 4×10^9 years, the other with ages of about 0.5×10^9 to 1×10^9 years[14]. Helium probably has been lost from the meteorites of the latter group. The potassium–argon ages for the same meteorites clearly indicate some loss of argon[14].

The accuracy of the cosmic ray age calculated from the potassium produced by spallation depends principally upon how well the ratio of the formation cross-sections for potassium-40 and -41 is known and the constancy of the cosmic ray flux. Nevertheless, this age of $0.6_9 \times 10^9$ years agrees remarkably well with independent age determinations for this meteorite and for other meteorites. Evidence is rapidly accumulating for the break-up of solid bodies and for the presumably related heating of at least some of the meteorites between 0.5 to 1.0×10^9 years ago. The comparison of potassium analyses from other iron meteorites may help to answer the question of whether these processes occurred throughout approximately half a thousand million years or during a much shorter interval.

I wish to thank Dr. R. H. Bieri and Dr. J. Geiss of this Institute for many discussions. This study was supported by a grant from the U.S. National Science Foundation.

Refraction of Very High Frequency Radio Signals at Ionospheric Heights

PEOPLE engaged in radio tracking of space vehicles are well aware of the fact that the Earth's atmosphere may cause serious refractive errors in the elevation angle determination It is also generally accepted that refractive errors rapidly decrease with an increase in the elevation angle, and become virtually negligible above 10 or 15 degrees In the case of radio astronomy, this is quite true However, in the case of space-vehicles, which travel in the immediate vicinity of the Earth, this is not the case The refractive errors due to the troposphere rapidly decrease with the elevation angle, while those due to the ionosphere initially increase with the elevation angle, and then gradually fall off This behaviour of ionospheric refraction is a necessary consequence of the spherical geometry The value of the elevation angle at which the maximum ionospheric refractive error occurs lies typically between 100 and 200 milliradians The exact expressions are rather involved, but it can be shown that the value of this angle is roughly proportional to the square root of the height of the layer The maximum value of the ionospheric refractive error is about 10–15 per cent higher than its value for a tangentially departing ray

Fig 1 shows a plot of the elevation angle error δ for realistic models of the ionosphere and troposphere The tropospheric calculations were based on radiosonde data The ionospheric calculations were based on a model of electron density profile which was parabolic below the region of the maximum density and was represented by the hyperbolic secant above the maximum The constants of the hyperbolic secant were adjusted so that the profile and its derivative were continuous everywhere, and the total electron content above the maximum was three times as large as below it This is in accord with experimental data based on Faraday rotation measurements[1] Details of the computational techniques are described elsewhere[2]

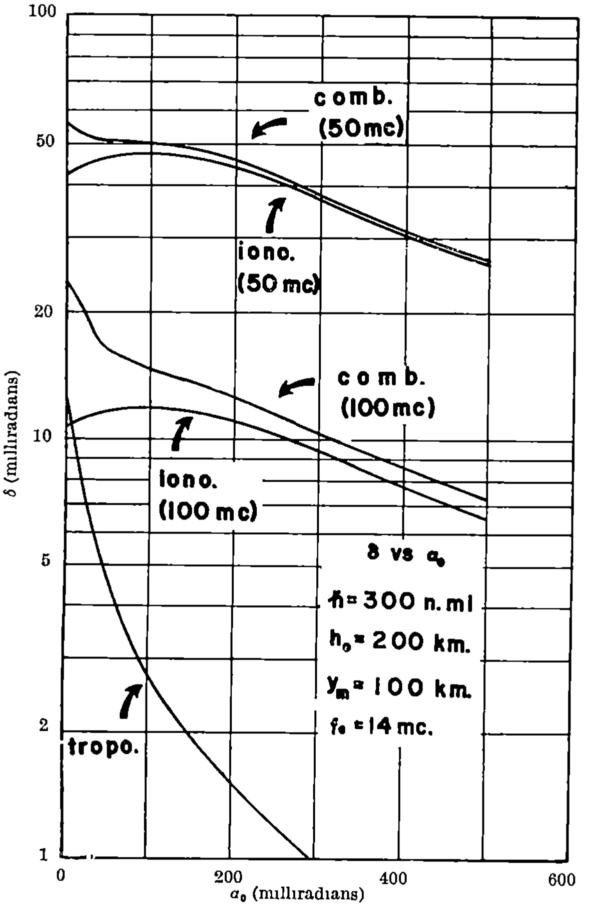

Fig 1

For the purpose of the accompanying illustration, the ionospheric constants were adjusted as follows height of the base 200 km , half thickness 100 km , critical frequency 14 mc , signal frequencies 50 and 100 mc The target height for which the refractive errors were computed was 300 nautical miles

Examination of Fig 1 shows that, at very low angles of elevation, α_0, the tropospheric refraction contributes appreciably to the refractive error while, at higher angles, the ionospheric factors predominate The peculiar behaviour of the ionospheric refraction manifests itself by the presence of the shoulder which is especially prominent at 50 mc , and also by the fact that the refractive error decreases more slowly with the elevation angle than might have been expected from the study of the refraction of radio stars

Near Infra-Red System of Nitrogen

IN the course of studying the molecular spectrum of nitrogen under various excitation conditions, Carroll and Sayers[1] discovered a new triplet transition in the near infra-red Only one band was observed as the spectral region of interest was dominated by bands of the first positive system A spectrogram of the new band was given together with measurements of the four strongest heads at 8265 5, 8283 8, 8293 3 and 8310 6 A The structure of the band was obviously complex, and it was suggested by Carroll and Sayers that the transition might be $^3\Pi - {}^3\Sigma$

More recently Kistiakowsky and Warneck[2] have reported bands of nitrogen in the infra-red, and these observations have been extended by LeBlanc, Tanaka and Jursa[3], who studied the emission from afterglows in argon–nitrogen mixtures at low temperature They also made a preliminary vibrational analysis and showed that the lower state was most probably $B\ ^3\ _g$

There is no doubt that the new system is the same transition as that reported by Carroll and Sayers This is proved by (*a*) the close similarity in structure between the 8265 5 A band on Carroll and Sayers's spectrogram and the bands in the spectrogram given by LeBlanc, Tanaka and Jursa , and (*b*) the agreement between the measurements of corresponding heads in the 8265 5 A band and the $(n + 1) - 1$ band of LeBlanc, Tanaka and Jursa

As the new system is of both theoretical[4] and astrophysical[5] interest the 8265 5 A band has recently been investigated under large dispersion It was photographed in the second order of the 21-ft grating in the Physics Department of University College, Dublin, and despite the weakness of the band and the presence of the first positive system, a rotational analysis proved possible Three components were found, each consisting of a fairly strong *P*, *Q* and *R* branch together with a number of weaker satellite branches A detailed examination of the results shows unambiguously that the upper state is of species $^3\Sigma^-_u$ A preliminary value of B_{n+1} determined from the *Q* branches alone gives 1 38_0 cm $^{-1}$ The analysis also verified beyond doubt that the lower state of the 8265 5 A band is the level $v = 1$ of $B^3\Pi_g$ This is shown by the excellent agreement between the combination differences derived from the present analysis and those formed from the data on the 1–0 band of the first positive system[6]

The vibrational numbering of the levels in the $^3\Sigma^-_u$ state is not known with certainty at present However, one can say that the $v = 0$ level cannot lie above about 71,700 cm $^{-1}$ and that it very probably lies within a few vibrational quanta of this value Now Mulliken[4], in his theoretical work on nitrogen, has predicted that a $^3\Sigma^-_u$ state, with a *B* value of approximately 1 47 cm $^{-1}$, should occur at about 70,700 cm $^{-1}$ It is seen that the results of the present work are in satisfactory agreement with Mulliken's theoretical predictions

A full account of the above work will be published elsewhere in the near future

Luminous Spots on Electrodes in Insulating Oil Gaps

In 1955 we reported the observation of luminous spots on electrodes in transformer oil[1] The spots were detected by a photographic plate in the oil between the electrodes with application of a c and d c voltage stresses for 2–30 min The oil was usually degassed but not filtered The luminous spots occurred at random on the surface of a plane electrode and were more concentrated at sharp edges One of the electrode systems used was an American Society for Testing Materials oil-breakdown test-cup The threshold average electric stress seemed to be of the order of 50 kV /cm minimum At the time of those experiments it was not known whether these luminous spots were due to discharges in tiny bubbles or to another cause.

Since those preliminary experiments, more refined and efficient techniques have been used in the investigation of these luminous spots, whereby the electrodes are observed face on through a glass window coated with transparent semiconducting tin oxide Microscopic examination has shown that, while bubbles do occur sometimes at high stresses under low hydrostatic pressures, or with fibres present, bubbles are not responsible for the luminous spots observed on electrodes in well-filtered, degassed oil The luminous spots have been shown to occur only at the negative electrode with d c stresses and are therefore attributed to fluorescence of the oil molecules excited by field-emitted electrons from points of high localized electric stress on the electrodes They have been detected by 10-min exposures with Ansco Super Hypan Film (*ASA* 500) in a camera having an *f*2 lens opening at a distance of about 5 in It is believed that these luminous spots are similar to the luminosity reported seen by Darveniza[2] at 600 kV /cm, but detected here at much lower average electric stresses The threshold voltage stress seems to be of the order of 50–250 kV /cm, depending on the degree of polish of the electrodes and filtering of the oil The local electric stress is very likely 10 or more times higher

M Wachtel (Westinghouse Research Laboratories, private communication) and Llewellyn-Jones[3] have reported electron field emission into a vacuum or low-pressure gas at average electric stresses of the same order as used here

The occurrence of luminous spots is not significantly affected by applied hydrostatic pressure from 10 mm mercury to 2 atmospheres They also occur with a c voltages between glass surfaces, indicating that field emission occurs from glass surfaces The luminosity is not affected by an efficient additive, benzil, reported by Basseches and McLean[4] to prevent gassing

It is believed that observation of these luminous spots assists in explaining the statistical effect of electrode area (and volume) on breakdown, particularly in commercial tests, and the dependence of long time a c electric strength on time of voltage application It also suggests the origin of the development of gas (hydrogen) in stressed oils, since the electrons exciting fluorescence (requiring about 3 eV) may also have or gain by acceleration sufficient energy to decompose the hydrocarbon oil molecules (requiring about 4 eV)

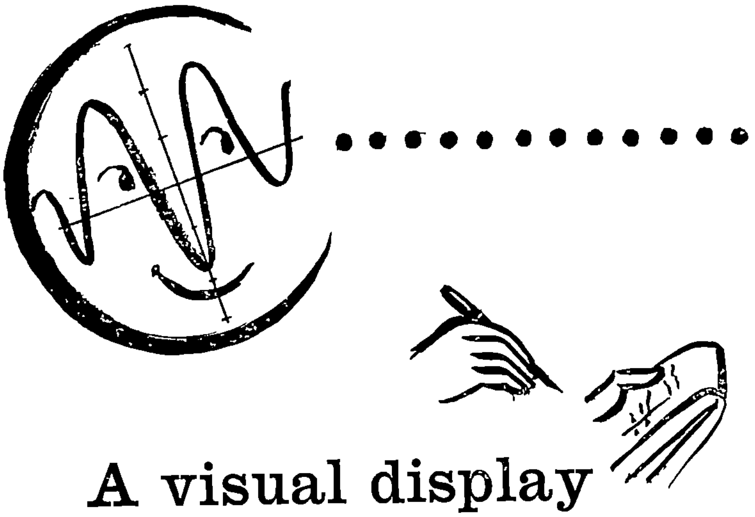
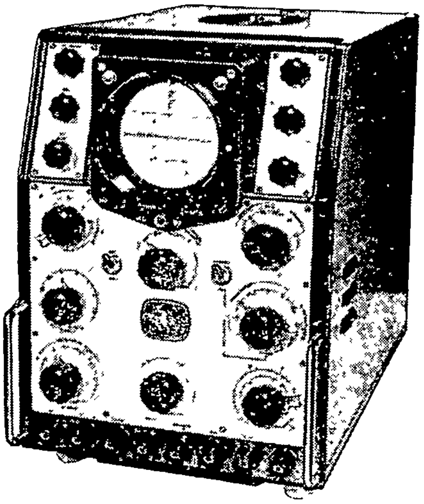
Compaction of Briquettes

When a powder is compacted by a simple application of pressure, the density and strength of the compact so formed (measured after the pressure has been released) are determined by the pressure used, but ultimately they approach limiting values which are not exceeded by further increasing the pressure The limiting density of the compact falls short of the density of the material of the powder by an appreciable margin, say 4–20 per cent, depending on the material used (Fig 1)

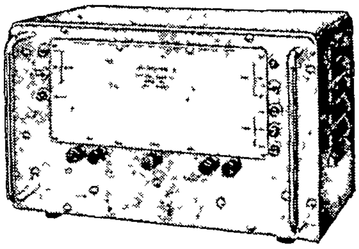
This failure to achieve complete compaction arises in two ways First, as the briquetting pressure is applied it is opposed by forces set up in the powder



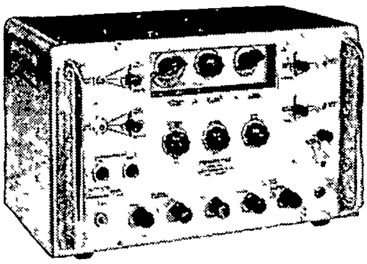


MODEL 1049 Mk. IV Oscillograph

A visual display of biological and physiological phenomena



MODEL 1327 Power Unit



MODEL 1440 Pre-Amplifier

Cossor Oscillograph, Model 1049 Mk. IV, is particularly suitable for biological and physiological investigations.

A double-beam instrument, its direct-coupled amplifiers will accept signals of frequencies from zero to approximately 0.5 or 1 Mc/s depending on channel and an overall sensitivity of 0.65 mV/cm is attainable through the A1 channel when used in conjunction with Pre-Amplifier, Model 1440, powered with transistorized Power Unit, Model 1327

A 7.5 sec. traverse is a feature of the time-base and beam bright-up facilities are available, together with full voltage and time calibrating circuits

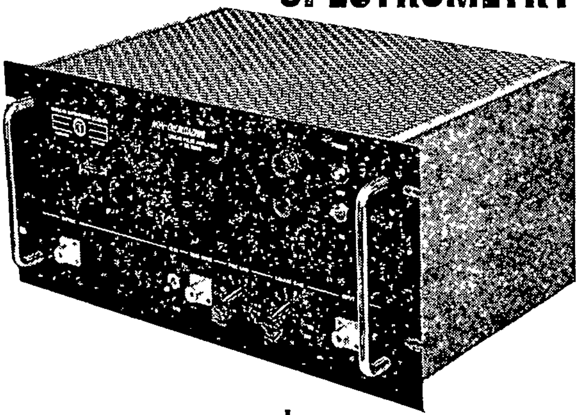
SCINTILLATION SPECTROMETRY



Non-Overloading Linear Pulse Amplifier NE 5202:

With 5 microsecond recovery for 100 times overload Designed for scintillation spectrometry and pulse height analysis studies, this amplifier features high gain (50,000), high gain stability (better than 0 25% per week), good linearity, low noise (less than 40 microvolts at input), excellent overload characteristics, and operation at high duty cycles Rise time 0 2 microseconds and integral linearity 0 15% Preamplifier NE 5202A also available Based on the double delay line differentiated Fairstein system, it consists of three high gain feedback groups and a White cathode follower output

Single Channel Pulse Height Selector NE 5102:

Resolving time, 1 2 microsecs, 3–140 volts operating range with energy zero drift less than 0 05 volts per day, 0 to 10 volt gate width with less than 0 01 volts per day drift, maximum counting rate, 2 × 10^6 c p

E.H.T. Supply Unit NE 5302:

With minimum of noise and ripple, output stability 0 01%, low noise and ripple—less than 1 mV RMS, output voltage continuously variable from 500—1,800 V, output current 5 mA

E.H.T. Supply Unit NE 5303:

As NE 5302, but with output voltage range from 1000—5000 V

Shielded Scintillation Head Units NE 5501 and 5502:

Containing White cathode follower preamplifiers with noise level of 25 microvolts, photomultipliers of 1 in or 2 in can be accommodated, for general use or for C^{14} and Tritium investigations with special rotary light locking device

Other Units Available:

Precision Ratemeter NE 5401 with eight ranges and six time constants
Scanning scintillation spectrometer NE 8601
Multi-channel scintillation spectrometer NE 8201 for industrial tracer investigations
Scintillometers for geophysical exploration
C^{14} and H^3 counting unit NE 8301

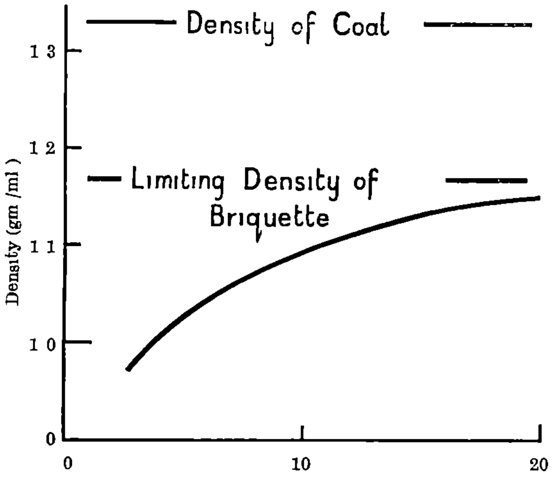

Fig 1 Betteshanger coal relationship between briquetting pressure and density of briquette

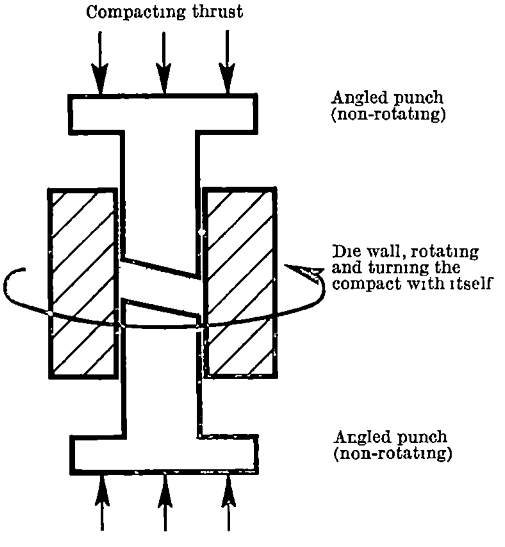
and upon the walls of the mould, which resist the movement of the particles and which resist the deformation of individual particles, these forces prevent intimate contact between the particle surfaces Secondly, as the external pressure is removed, the deformed particles recover their shape elastically, in part at least, and the compact expands and the voids within it increase A large elastic recovery is associated with a weak compact

It has been found that if the powder compact, while still under load, is subjected to shear strain, (as for example in a rotary shearbox as sketched in Fig 2) there is a further compaction without any further increase in pressure being required Also, the elastic recovery of the compact when constraints are removed is reduced The compact made in this way is stronger than one made by simple pressing at the same pressure, and may possess greater density and strength than the limiting values obtained by simple pressing Whether the compact is made by simple pressing or by introducing additional shear strain under load, the strengths and densities are still related by the same single curve The gain in strength may be substantial, and with coal powders a five-fold increase has been attained. The full benefit is obtained only if the shear strain is introduced under maximum load (Fig 3)



Compacting thrust
Angled punch (non-rotating)
Die wall, rotating and turning the compact with itself
Angled punch (non-rotating)

Surface of contact between punches and compact are lubricated to allow the compact to rotate within the die wall

Fig 2 Action of a rotary shearbox

The response to the introduction of additional shear strain under load varies with the material In a material such as 'Plasticine', which deforms plastically very readily and which has negligible elastic recovery, the process offers no advantage Natural graphite powder also compacts readily, and reduces to a compact of about 4 per cent porosity by simple pressing , here again there is little advantage in applying extra shear strain, which may do more harm by disrupting the briquette than good by compacting it At the other extreme, anthracite powder, which shows an elastic recovery of 30 per cent while still in the die in which it has been pressed, forms no compact at all, with or without extra shear strain The advantage of the process is found with materials lying between these extremes The coal, the properties of which are illustrated in Fig 3, is an example , the introduction of extra shear strain improves the compaction of the final briquette by about 10 per cent porosity, and the strength by a factor of 3–5

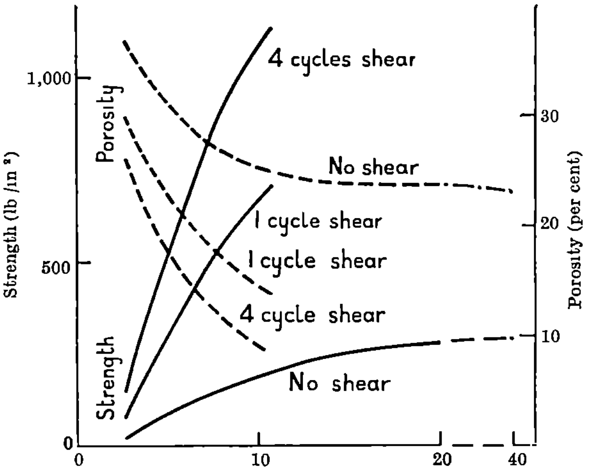


Fig 3 Sherwood coal relationship between briquetting pressure, shear strain, strength and porosity (shear strain introduced in cycles of amplitude 8°)

The adhesion of particles in these non-metallic compacts is not yet fully understood, nor is the action understood whereby shear strain improves the adhesion The fact that a single strength–density relationship applies to all compacts made from a given powder, with or without extra shear, suggests that no new mechanism of adhesion is introduced by shearing

Association between Colour of the Iris of the Eye and Reaction to Dental Pain

An association has been found to exist, in Australians of European stock, between the colour of the eyes and the reaction to pain resulting from dental cavity preparation.

At the present stage of this study, examination has been made of 403 consecutive subjects whose teeth were being prepared for filling, the cavities being cut by means of the Borden high-speed air-rotor apparatus. Their ages ranged from three years to more than fifty years.

The pain reaction of each subject was assessed, four classes being used: subjects that showed (*a*) no pain reaction during the preparation of the cavity, (*b*) a slight reaction, (*c*) a marked reaction and (*d*) those whose reaction was so great as to require the injection of a local analgesic. After having recorded the pain reaction of a subject, the colour of the iris was observed, nine categories, ranging from blue to dark brown, being recorded. The pain-reaction classes were given arbitrary values of 0–3, and the colours of the iris, values of 1–9.

The association between these factors is highly significant, but, of course, is considered to be due to their joint association with other factors. The accompanying graph (Fig. 1) of mean values displays the association between pain reaction and colour of iris.

Each point of the graph is based on more than 40 observations, with the exception of the last three, for only 11 subjects were seen with light brown eyes, 23 with brown and 28 whose irises were dark brown.

Judgement of the reaction to pain is based on 12 months use of this new apparatus (Borden high-speed air-rotor), and on more than twenty years clinical experience; nevertheless, it is acknowledged that both types of observation are open to criticism owing to their subjective nature. However, a test to establish the reproducibility of the results was satisfactory, for out of 136 subjects that were re-assessed between one and four weeks after the original examination, the same values were obtained for the colour of the eyes in 115 cases, and for the pain reaction in 114 subjects. Both for colour of iris and for pain reaction, the mean of the discrepancies between each pair of results was non-significant; the mean discrepancies were, pain reaction 0.02, iris colour 0.04.

Approximately 13 per cent of the total number of subjects required the injection of a local analgesic for cavity preparation, a similar percentage being found in the group of subjects formed by adding the results of those whose eyes were greyish-green, green or hazel. However, this aid was not required by any blue-eyed subjects, and was used for only 2 per cent of those with greyish-blue or greenish-grey eyes; but it was required by 30 per cent of the subjects with light brown or brown eyes and by more than 53 per cent of those whose eyes were dark brown.

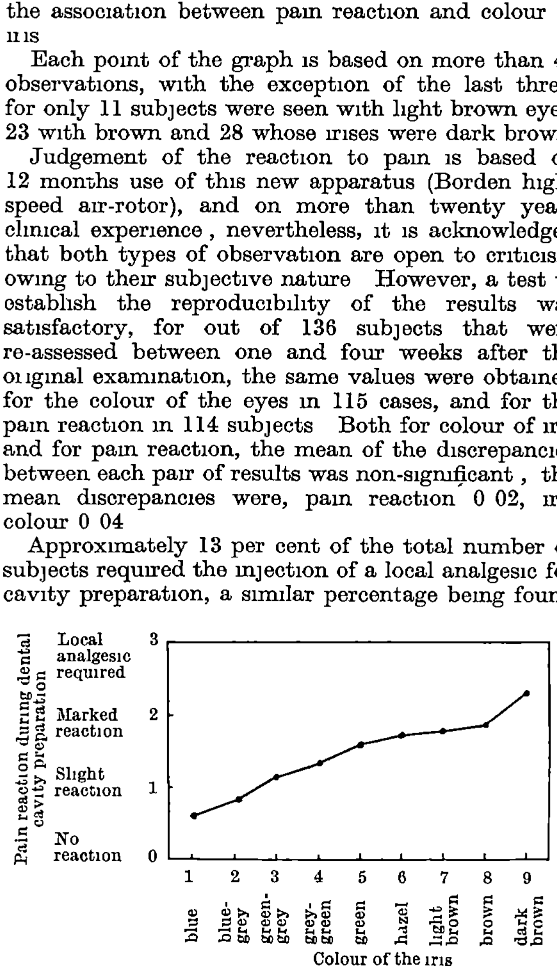

Fig. 1. Association between the colour of the iris and the reaction to pain resulting from dental cavity preparation

Development of the Aplacophorous Mollusc *Neomenia carinata* Tullberg

Present-day authorities agree that, within the Mollusca, the chitons (or Polyplacophora) are closely related to the solenogastres (or Aplacophora). An important item influencing this view is the description, by Pruvot[1], of the development of seven overlapping, dorsal, plate-like spicules in the metamorphosing larva of the solenogastre, *Nematomenia banyulensis*. The appearance of these spicules has been considered to be a reminiscence of a chiton-like ancestor and, no doubt, has influenced many authors in coming to the conclusion that the solenogastres are degenerate chitons. Pruvot's description was based on observations on a single larva, but nonetheless the figure he gave of this developmental stage has been widely reproduced in general works.

The purpose of the present communication is to describe some observations on the development of *Neomenia carinata* Tullberg 1875; together with the work of Baba[2] on *Epimenia verrucosa*, they show clearly that, while the larva of *Nematomenia* may develop overlapping dorsal plates in the manner described by Pruvot, this is by no means the rule in the Aplacophora.

The embryos of *Neomenia carinata* hatch three days after oviposition (at 10° C.) as trochophores with the blastopore still open abapically, but with no stomodaeum yet developed (Fig. 1*A*). These larvæ swim over the bottom of the culture vessel, propelled by the strong cilia of the prototroch. As the larvæ proceed, they spiral in the same direction as the metachronal waves travel around the prototroch (clockwise when viewed from the anterior). At 7–8 days metamorphosis begins; a caudal bud begins to protrude through what was formerly the blastopore (Fig. 1*B*). The tip of this bud bears a minute pore, the anus, and is ciliated. The rest of the bud, as it grows out, is unciliated but bears large numbers of pointed spicules (Fig. 1*C*). The 'trochophore' part of the larva remains ciliated, but becomes reduced in size, while the prototroch and apical tuft degenerate. The caudal bud comes to form by far the greater proportion of the larva (Fig. 1*D*). The last remains of the ciliated trochophore-mass are ingested through the mouth as the larva completes metamorphosis (Fig. 1*E* and *F*) and abandons pelagic life. At no time is there any trace of segmentation, nor of any dorsal shell-plates. When metamorphosis is complete the external surface of the body (except perhaps for the pedal groove) is unciliated, and the form is like that of the adult *Neomenia*.

This description is based on observations on large numbers of larvæ of *Neomenia carinata* reared through metamorphosis in the laboratory, and the

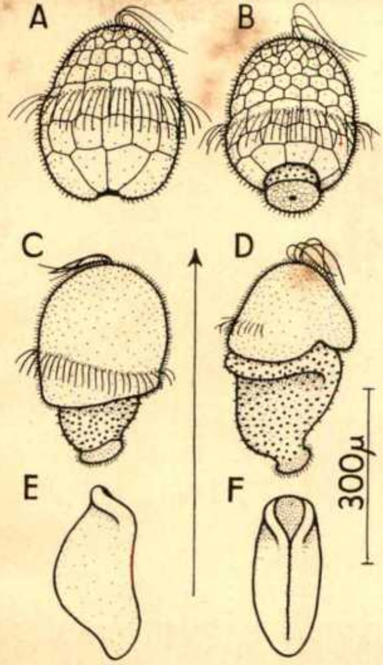

Fig. 1. Metamorphosis of *Neomenia carinata* (camera lucida drawings of live larvæ). *A*, Trochophore at 3 days; *B*, trochophore at 9 days, ventral aspect; *C*, trochophore at 10 days, right lateral aspect; *D*, trochophore at 11 days, right lateral aspect; *E*, newly metamorphosed stage (12 days), right lateral aspect; *F*, the same, ventral aspect. In *E* and *F* the spicules are not illustrated. The arrow shows the antero-posterior axis of the animals

results so far obtained plainly show the need for a re-investigation of the development of *Nematomenia*. At present, the indications are that the nearest relatives of the Aplacophora within the Mollusca may be found in the primitive Lamellibranchia rather than in the Polyplacophora. The resemblances in development between the solenogastres and members of the Brachiopoda, Archiannelida and Nemertea (to which various authors have directed attention) are probably without profound significance. The work on *Neomenia* is being continued and is financed by a grant from the Leverhulme Trust.

Dagger Nematodes associated with a Clover Sickness

DAGGER nematodes (*Xiphinema* spp.) are now recognized as important crop pests in many North American states[1-3] and occur widely in tropical countries[4,5] in close association with plant roots. Because of their migratory ectoparasitic habit they are seldom observed feeding on the host plant, and where they appear to be associated with crop damage pathogenicity is difficult to prove.

Examination in early February of 'sickly' white clover (*Trifolium repens* L.) plants from a clover ley near Crewkerne, Somerset, showed no pathogenic organism, but large numbers of dagger nematodes were recovered from the soil around the roots. The roots themselves bore minute lesions compatible with nematode feeding, and many young rootlets were brown and shrivelled at the tip. The field, a sandy loam, had been sown to grass and clover leys in seven out of the past ten years and had a similar early history.

The area was again sampled at the end of April, by which time the clover was dying off in patches. Many dagger nematodes were again recovered, but fungal damage was also evident and small sclerotia, believed to be those of *Sclerotinia trifoliorum* Erikss., were seen; the stem eelworm *Ditylenchus dipsaci* Kühn also occurred in numbers sufficient to constitute a possible cause of disease.

The exact role of dagger nematodes in this complex is thus uncertain; this is the first record of the genus *Xiphinema* in Great Britain, and observations and measurements suggest that the specimens recovered represent a new species, which will be described elsewhere.

Pollen of *Acacia* from Tufaceous Limestone near Udaipur

I HAVE undertaken the investigation of fossil microflora from a tufaceous limestone near Udaipur. This fossiliferous locality is about three-quarters of a mile north-west of the tenth milestone on the Udaipur–Gogunda Road. It was first described by Murty[1], who had suggested a tertiary age to these beds.

A few pieces of fossil were macerated with Schultz's solution and clear dehydrated mounts were prepared by passing the material through various grades of alcohol and mounting in Canada balsam. Some of the preparations were stained with safranin. The

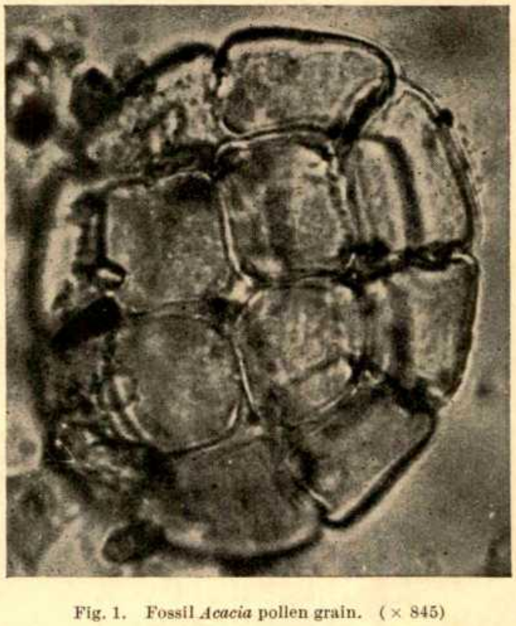

Fig. 1. Fossil *Acacia* pollen grain. (× 845)

slides so prepared showed many angiospermic pollen grains, some of which belong to the Leguminosae and the Gramineae. Also a few pteridophytic spores were observed.

One well-preserved pollen grain resembles very closely that of *Acacia longifolia*. It is a smooth compound 16-celled grain; eight cells are centrally placed, forming a sort of cubical block with the others arranged in a rectangular fashion. The central group is surrounded by eight peripheral cells all in a plane at right angles to, and bisecting, the central group. The peripheral cells are so placed that their eight contacts with each other are alternately opposite and midway between the four contacts of the central group. The group as a whole is flattened, with a more or less rounded outline, and the intersecting lines between the individual grains cross each other at right angles.

The exine is thick and its corners are rounded. The individual grains measure about 24·5μ in diameter and the whole compound grain is 69·5μ in diameter.

It is significant to note that fossil pollen grains of the *Acacia* type have been recently described from the Victorian Tertiary deposits, Australia, by Cookson[2].

I thank Dr. Chitley for her guidance in this work.

ARCHÆOLOGY

Stone Implements from Western Nigeria

RECENTLY a number of stone implements have been uncovered by labourers in sand quarries at Green Springs near Ibadan, Western Nigeria. These implements are associated with deposits of river sand and clay. The workmen wash the sand, discarding the clay and stones, usually placing the latter in heaps or scattering them about the ground. Thus it has not been possible to determine the level at which they were lying before excavation. Generally, however, the layers containing stone are between one and seven feet below the main surface-level.

Table 1 lists the definite artefacts found. The material is mainly quartz from the basement complex.

Polished stone axes are common in Nigeria, where they are often used as protective charms against thieves and thunder, in the belief that they are fallen thunderbolts. Flaked and tanged implements, however, have not previously been recorded from the Western Region of Nigeria, although flaked implements which have been compared to the Chelles–Le Moustier epoch in Europe are found in Northern Nigeria[1], and other flaked implements have been reported from the Eastern Region and the Cameroons[2]. Typologically, the Green Springs implements fall into two groups: (*a*) neolithic types, represented by stone balls, polished axes, anvils, and grinding stones; and (*b*) palæolithic types, represented by the points, the flaked axes and the tanged blade. The latter are suggestive of the Aterian cultures of North Africa[3,4].

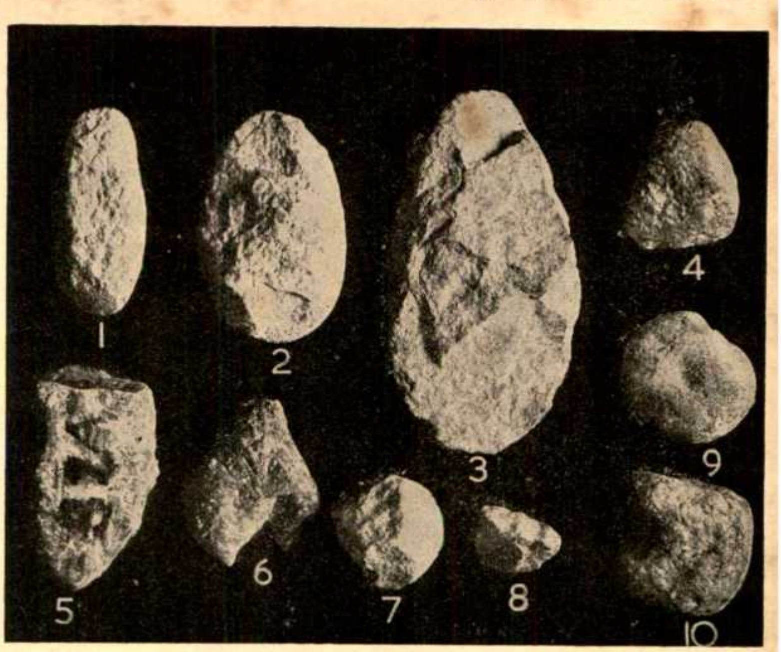

Table 1

Description	Dimensions	No.
Polished hand axes, Fig. 1	Approx. 12 × 6 × 2½ cm.	5
Fragments	Average width : 6 cm.	10
Well-formed bifaced hand axe, Fig. 2	14 × 9½ × 5 cm.	1
Unifaced hand axe, Fig. 3	23 × 12½ × 4½ cm.	1
Polished cleaver-like stone, Fig. 4	7½ × 7 × 3½ cm.	1
'Points', Fig. 5	Approx. 13 × 9 × 2½ cm.	2
Tanged unifaced blade, Fig. 6	11 × 9 × 2 cm.	1
Hand-held polishing or grinding stones, Fig. 7	Approx. 7 × 6 × 6 cm.	3
Bifacial discoid stones (scrapers ?), Fig. 8	Approx. 4 × 6 × 2 cm.	2
Anvil stones indented both surfaces, Fig. 9	Approx. 9 × 7 × 4 cm.	4
Balls	5–8 cm. dia.	15
Eccentrically perforated stone, Fig. 10	Width, 8 cm. ; perf., 2 cm.	1
Fractured stone cylinder	6 cm. dia.	1

We are of the opinion that systematic excavation in the area may be of advantage to pre-history. We wish to acknowledge the kind help of Mr. R. Hockey, geologist, Geological Survey Department, Federal Government of Nigeria.

At 11 30 a m —Prof Magdalen Vernon "Perception, Attention and Consciousness" (Presidential Address, Section J)

At 8 p m —Prof M Swann "The Unseen Pattern of Growth" (Evening Discourse)

Sunday, September 6

At 10 30 a m —Official Service at York Minster Preacher The Most Reverend The Lord Archbishop of York

Monday, September 7

At 10 a m —Prof O M B Bulman, F R S "Recent Developments and Trends in Palæontology" (Presidential Address, Section C)

At 10 a m —Prof Ian A Richmond "The Nature and Scope of Archæology" (Presidential Address, Section H)

At 10 a m —Prof A Hemingway "Artificial Organs—Biological Applications" (Presidential Address, Section I)

At 8 p m —Sir William Hildred "International Air Transport Problems" (Evening Discourse)

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned

Analyst (qualified for general inorganic analysis) in the Houldsworth School of Applied Science, mainly for work on silicates—The Registrar, The University, Leeds 2 (August 31)

Lecturer in Mathematics , Lecturers (2) in Geography , and Lecturers (2) in Education at Palmerston North University College, (Victoria University of Wellington), New Zealand—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W C 1 (New Zealand, August 31)

Lecturer (preferably with experience in solid-state or low-temperature physics or ultrasonics) in Physics—The Registrar, Queen Mary College, Mile End Road, London, E 1 (August 31)

Assistant Lecturer (preferably with interests in plant physiology and plant ecology) in Botany—The Principal, Royal Holloway College (University of London), Englefield Green ,Surrey (September 1)

Senior Lecturer and Director (with high academic qualifications and experience of high-speed digital computers) of the Sub-Department of Computation—The Secretary and Registrar, The University, Southampton (September 1)

Assistant Lecturer or Lecturer in the Department of Agricultural Economics—The Registrar, University College of Wales, Aberystwyth (September 5)

Laboratory Steward in the Department of Botany—The Registrar, University College, Singleton Park, Swansea (September 8)

Lecturer in Zoology in the University of Queensland, Australia —The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W C 1 (Australia, September 11)

Assistant Lecturer in Dairying—The Registrar, University College of Wales, Aberystwyth (September 12)

Lecturer in Pure Mathematics , Senior Tutors (2) in Pure Mathematics , and a Senior Lecturer in Physical Metallurgy at the University of Sydney, Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W C 1 (Australia, September 19)

Lecturers (2) in Astronomy in St Salvator's College, University of St Andrews—Joint Clerk to the University Court, College Gate, St Andrews (September 19)

Lecturer in Education at the University of Otago, Dunedin, New Zealand—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W C 1 (New Zealand, September 20)

Senior Tutor-Demonstrators (2) in Zoology at the University of Sydney, Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W C 1 (Australia, September 26)

Lecturer in Mathematics at the University of New England, Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W C 1 (Australia, September 30)

Lecturer in Geography at the University of Sydney, Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W C 1 (Australia, October 1)

Mycologist (with a good honours degree in botany, with mycology as a special subject, a knowledge of the more fundamental aspects of animal and human mycoses, and preferably a knowledge of Latin and other languages) at the Commonwealth Mycological Institute, Kew—The Secretary, Commonwealth Agricultural Bureaux, Farnham House, Farnham Royal, Bucks (November 30)

Junior Plant Breeder (male, with a good honours degree in botany with postgraduate experience in the technique of plant improvement) at the West African Cocoa Research Institute (serving initially at Tafo, Ghana), to carry out research on plant-breeding problems relating to cocoa—The Director of Recruitment, Colonial Office, London, S W 1, quoting BCD 197/200/08/T

Lecturer in Physics, and an Assistant Lecturer in Physics (Grade "B')—The Clerk to the Governors, Northern Polytechnic, Holloway, London, N 7

Senior Lecturer in Zoology—The Registrar, Bradford Institute of Technology, Bradford 7

Technician in the Zoology Department—The Secretary, Royal Holloway College, Englefield Green, Surrey

SCIENCE AND SOCIETY

IN an address at the California Institute of Technology on June 12, the substance of which appears on p. 135 of this issue, Sir Solly Zuckerman remarked that the element of the unknown in government increases with every step we are now taking to apply the fruits of science, and that if, as some consider, sovereign power is being abrogated, it is not to some governing body, however formed, but more and more to a process of applying scientific knowledge without any real possibility of determining its final consequences. Dr. Brian Chapman closed his recent book, "The Profession of Government"*, with the remark that in the past hundred years in Europe arbitrary power has been replaced by anonymous power, and anonymous power is the antonym of public administration. It is, in fact, in the context of the problem of government that Sir Solly approaches his subject of liberty in an age of science, and the second main point to which he directs attention is that science, itself demanding freedom and revolutionary in its ways, is now determining, in an increasingly unpredictable way, the main issues about which citizens exercise their freedom of choice. This involves consideration of both the means and the purpose of government.

Sir Solly Zuckerman begins in a way which recalls Sir Charles Snow's Rede Lecture, and also Dr. P. A. Weiss's address, "The Message of Science", at Brussels last year, by discussing the divergence between the scientist and the humanist, quoting George Gissing's fear that science would become the remorseless enemy of mankind, before he goes on to explain the nature of science itself and of its dependence on freedom. For the scientist this means not only the freedom to choose his own problems to investigate, but also the fact that significant advances in scientific knowledge cannot be ordered by decree. Because scientific advance is unpredictable, "the untrammelled emergence of new scientific ideas is not compatible with any restraint on the liberty of the scientist to roam where his fancy leads. Indeed, once the growth of any set of scientific ideas becomes constrained, they are in danger of becoming obstructive dogma".

It is this freedom of science even to be revolutionary that raises doubts and even controversy if stability is to be achieved in a world in which the impact of science is so profound, and Sir Solly Zuckerman points that out; while the growth of fundamental scientific knowledge necessitates complete freedom from restraint, science is not uniquely associated with the preservation of freedom either in the personal or the social sphere. The applications of science have indeed provided the apparatus which has made central government powerful alike in a democratic and in an authoritarian regime. Science itself has no inherent moral direction, and while science will be the handmaiden of equality in the economic sphere, given the appropriate political institutions, our social environment is constantly being transformed by new scientific ideas and by the application and practical development of those ideas.

It is in this way that science helps to define for us the content and boundaries of the area within which we exercise our freedom; and in this sense only, the sense in which freedom was conceived by the utilitarians of the industrial revolution, science can be described as the handmaid of freedom. Through its practical impact, science to an increasing—almost to a dominant—extent is determining the way in which the sovereign power expresses itself, and here Sir Solly asks whether in choosing to regulate our lives in accordance with scientific discovery we know for what it is we are opting. "Is the sovereign power consciously deciding to develop this or that scientific discovery, and so to determine social development in this or that direction ?"

The answer to any of these questions is inevitably bound up both with the constraints and the unpredictability of any major scientific advance. Moreover, as Sir Solly himself reminds us, scientific knowledge never develops evenly over the whole potential field of knowledge, and by choosing one out of several possible courses of action in search of a solution to a problem, the scientist may deny himself, and others, the opportunity of pursuing another. That applies still more to the choice of problems to be investigated, as the recent debate over Britain's decision to enter the field of space research should sufficiently illustrate, and beyond difficulties due to the increasing complexity of scientific knowledge and its application lies the impossibility of defining in advance the nature and magnitude of potential discovery or its impact on our social lives. Moreover, there may well be unforeseen and unexpected secondary social effects, as is well illustrated in Dr. Michael Young's discussion of possible effects of selection on the basis of intelligence tests in his book, "The Rise of the Meritocracy". Well may it be asked whether there can be much more than a fictional verity in the abstract idea that an area exists within which men can enjoy the capacity of unconditioned or untrammelled choice.

Sir Solly seems to recognize clearly enough that this is ultimately a problem of government rather than of philosophy. His remark that the only form of exploitation which democracy—man's answer to tyranny and exploitation—will never overcome is the coercion of new knowledge, which, by guiding our social lives into certain channels, limits advance in other directions, should be pondered in the light of the clear warning about the dangers of secrecy which Dr. Brian Chapman gives in his final chapter. Dr. Chapman is exposing the stupidity of secrecy from the point of view of relations between the government and the public All that he writes, however, about the futility of the pathological secretiveness of the British Government, matched in Europe only in Spain and Portugal, applies even more forcefully where science is concerned These attempts at secrecy merely hinder scientific or technical advance without promoting security and, more serious, impede the informed public discussion and understanding of what both science and Government are doing which is essential if science is to be wisely used

---

* The Profession of Government: The Public Service in Europe. By Dr. Brian Chapman. Pp. 352. (George Allen and Unwin, Ltd., 1959.) 28s. net.

This is even more important now that we stand at the cross-roads, as Sir Solly reminds us Hitherto, we could claim that the applications of science have increased the sum total of human happiness The process of applying scientific knowledge is as endless as is the prospect of getting new knowledge, and we can be reasonably certain that neither the backward and under-developed nor the rich nations will allow the process of applying the fruits of scientific knowledge to stop, either in the national or the international framework In this process, however, means become ends, because as new ways of doing things are discovered, they transform the things done, and so their purpose In fact, weapons may end by determining strategy and even the purpose behind the strategy

Here, in Sir Solly's view, arises the real clash to-day between the scientist and the humanist, and this form of scientific application could indeed constrain our democratic liberties and even, if we ceased to be vigilant, the liberty of science itself That would seem to imply a special responsibility for the scientist, though Sir Solly does not agree that such a responsibility means more than that the scientist is better able to appreciate scientific facts It is not reasonable, he points out, to expect the scientist as such, who is not responsible for the application, to accept the responsibility for predicting some vast social transformation which might result from a seemingly innocent observation

Nor is that all, for it has to be remembered that the process of government involves much more than taking account of scientific and technical factors and their implications Even if the problem is essentially a scientific one, the statesman or minister who has to take a decision and formulate a policy must have regard to public acceptability, and accordingly to the public understanding Normally there will be many other factors to be considered, and it is the consequences of the application of science that are of most concern, since they are most readily appreciated by the public and most relevant politically

It is noteworthy that in this connexion Sir Solly Zuckerman reaches the same conclusion as to the importance of education as do Dr Chapman and Mr C H Sisson in another recent book on government* Sir Solly suggests that in this problem of preserving our liberties lies the most important reason for regarding an education in science as constituting to-day an essential part of an education in the humanities An understanding of social and political purpose can no longer be realized through the liberal arts, unless their scope is widened to embrace a proper understanding of the scientific knowledge the application of which is so rapidly transforming our intellectual and material environment

It is with realism and not arrogance that Sir Solly places science, technology and humanism in that order of importance in determining our affairs , and in the same spirit that he suggests that, to continue as a potent educational discipline, the humanities must encompass an understanding of the social forces which arise from the application of the natural sciences Nor does he suggest that higher education necessarily guarantees higher virtue or higher political wisdom , rather we are likely to avoid bad decisions if we realize that decisions taken in major scientific matters to-day may determine the course of the future Dr Chapman comments that no other European country has emphasized to the same extent as Britain the strange division between science and the humanities, with the result that the common difficulty of finding adequate numbers of Civil servants with sufficient specialized training is accentuated , nevertheless, he recognizes that all branches of the public service, ministries as well as industrial public enterprises, need a proper balance between administrator, manager and technician, and that ministries often lack technical competence in scientific, industrial and economic fields

Apart, however, from referring to the way in which France has been able to meet some 90 per cent of her requirements for first-class engineers and technologists with administrative experience, Dr Chapman does not discuss the place of the scientist or technologist in administration He stresses the importance of education and recognizes that this means the education of the general public as well as of the administrator, and the politician and minister He makes the significant comment that a menial mind should not be a qualification for high administrative office , but his constructive criticism is rather on the structure of the Civil Service itself, where it points to the fresh thinking that is required in order that the public services may be able to fulfil the needs of the modern State

Nor are his suggestions for the Civil servant or the minister alone they are no less worthy of the attention of professional organizations, for they point to ways in which not merely could the public services be absorbed more effectively into the structure of the modern State, but also, and no less important, the professional scientist or technologist could serve the State under conditions less likely to constrain professional ideas and tradition Mr C H Sisson, in "The Spirit of British Administration", is less confident as to the possibility of a general liberality, though he believes just as firmly as Sir Solly Zuckerman and Dr. Chapman that the survival of some kind of liberal and general education is indispensable to the survival of parliamentary government or indeed of any government based on free discussion, with this goes the survival of administrators who are not daunted by specialists but take it for granted that the practical implications of all their work can be explored and explained by a sufficiently agile lay mind

---

* The Spirit of British Administration and some European Comparisons By C H Sisson Pp iv+162 (London Faber and Faber, Ltd , 1959) 21*s* net

The defence of freedom is a central problem of our time, and it is not simply one of defence against aggression from totalitarian systems outside Sir Solly Zuckerman shows clearly how it arises from the nature of science itself, and from the impact of science on society Any scientist or technologist who is concerned about those changes and how they can be best avoided or minimized will be led inevitably to think not simply about the association of scientist or technologist with government but about the process of government itself To such thinking both the books mentioned above offer some contribution in different ways they can assist in the understanding of the nature of administration and the limitations within which the administrator works, they indicate also the mind of the administrator and how it is trained or formed, and they point to some of the ways in which reform or developments are required if the task of government is to be discharged adequately to-day But, like Sir Solly Zuckerman's address, they are primarily a challenge to the scientist or technologist to accept such responsibility to-day, and a stimulus to the creative thought by which alone that responsibility can be discharged

THE NEED FOR MARINE RESEARCH

Living Resources of the Sea

Opportunities for Research and Expansion By Dr Lionel A Walford (A Conservation Foundation Study) Pp xv+321 (New York The Ronald Press Company, 1958) 6 dollars

IT is more than sixty years since the foundation of the International Council for the Exploration of the Sea, the avowed purpose of which is the accumulation of knowledge necessary for the rational exploitation of marine resources in northern waters There are now a dozen or more councils or commissions covering other areas of the world, including commissions limited to certain animals, such as halibut, salmon, tuna, and whales The fear of over-fishing, which has been the spur to the activity of the International Council, the Halibut Commission, and other more recently formed organizations, has always been well to the fore in the minds of those concerned with the science of the sea The necessary research has been concentrated on the main northern fisheries, but now the demand to feed the under-nourished millions has focused attention on the sea as a whole as a possible source of protein

At the request of the Conservation Foundation, Dr Lionel A Walford, chief of the Biology Branch of the U S Fish and Wildlife Service, was asked to explore the question "What scientific researches, apart from those which are in progress, would contribute significantly toward learning how to enlarge the yield of food from the sea in answer to human needs ?" This has resulted in a useful book in which Dr Walford considers the problem from human and biological angles The major conclusion is that research must be extended into those areas where the need is greatest, and where there is the most possibility of increasing the food supply where it is most lacking A number of interesting charts are included indicating the existing intensity of fishing and research in different parts of the world, those areas of the sea which might be expected to be productive, and those on land where the need for food is greatest This survey impresses on us that where the fisheries are at present most developed and exploited there lies the major effort of research The number of pertinent marine laboratories is now about 240 Nearly 90 per cent of these are in the northern hemisphere and 85 per cent north of latitude 20° N Thus, those areas in which the need for research is now greatest have least facilities to do so both in material equipment and trained personnel The problem is one both of research and development, and it is not easy to do the former without the latter unless exploration for fishing grounds is subsidized by governments

It is thus both humanely and politically advisable that the countries most advanced in marine research should do their utmost to help the under-developed areas Since the Second World War fisheries research under the auspices of Her Majesty's Colonial Office has added significantly to knowledge in certain areas, the U S Fish and Wildlife Service has extended its investigations into the oceanic pelagic fisheries, and the United Nations Food and Agriculture Organization has helped in supplying experts and supervising training But this effort should if possible be much increased, and every encouragement given to those who wish to do research that will add to our knowledge of conditions in tropical seas

Dr Walford's book is not a text-book, it attempts to show where lie the gaps in knowledge, and these are both large and numerous As a single example, what do we know of the probably enormous food potentialities available in pelagic cephalopods which now constitute 60 per cent of the Japanese fisheries ?

Marine resources are also not necessarily all of value as food, some may have medical value On our own planet there lies a whole world which we have only recently begun to study extensively. It is to be hoped that Dr Walford's book may stimulate us to greater efforts.

F S. RUSSELL

ANOTHER DEBT TO DARWIN

Index Kewensis

Plantarum Phanerogamarum Supplementum Duodecimum Nomina et Synonyma Omnium Generum et Specierum ab Initio Anni MDCCCCLI usque ad Finem Anni MDCCCCLV Nonnulla etiam antea Edita Complectens, Ductu et Consilio Georgii Taylor, confecerunt Herbarii Horti Regii Botanici Kewensis Curatores Pp iii+157 (Oxonii E Prelo Clarendoniano, 1959) 75*s* net

IN this centenary year of the publication of the "Origin of Species" biologists have very much in mind the debt that they owe to Charles Darwin It is probable, nevertheless, that many of them do not remember that the inception of "Index Kewensis" was due not only to Darwin's perception of the necessity for such a work but also to his generosity in providing the funds

We might at this moment remember that the work was started under the supervision of Darwin's great friend, J D Hooker, and has since been supervised by subsequent directors of Kew and carried out by numerous able, but often anonymous, helpers

"Index Kewensis" is taken so much for granted by plant taxonomists working with angiosperms that it is often not fully appreciated To anyone who has struggled, even briefly, with taxonomic and nomenclatural problems in groups such as algae, where no such index exists, the lack of it is keenly felt and the value of a catalogue of names with places of publication is soon fully realized It is interesting to note in this connexion that an "Index Muscorum" is due to be published shortly—another descendant of the original Darwinian idea

"Index Kewensis", the twelfth quinquennial supplement to which has now been published under the direction of Dr G Taylor, supplies far more information about flowering plants and papers concerning them than might at first sight appear

For example, in the five-year period between 1951 and 1955 approximately 12,000 species of flowering plants have been described This, after more than two centuries of taxonomic work in the post-Linnean period, is a staggering total and gives some measure of the imperfection of our knowledge of the dominant group of plants

It is also easy to obtain from these Supplements references to important monographs and information about the geographical areas and the plant groups which have been the subject of special attention in the recent past, as well as the names of the workers concerned

In conclusion, I may perhaps be allowed to repeat what has so often been said before "Index Kewensis" is indispensable T G. Tutin

OPTICS: CLASSICAL AND MODERN

Concepts of Classical Optics

By Dr John Strong Pp xxii+692 (San Francisco W H Freeman and Company, London Bailey Bros and Swinfen, Ltd, 1958) 9 50 dollars, 80*s*

THIS is a very good book, and one of its best features is the care taken by the author to ensure that the student understands what is going on Mathematical treatment is kept to a minimum, but where it is necessary we are not left to flounder, the author explains what he is doing by means of a sort of running commentary, and even reassures us that although the solution we are after is buried in complication at the moment it is going to emerge safely in a minute The only criticism here is that some simplification of the symbols used would lead to even greater clarity, for example, why was it necessary to use the symbol λ for mass early in Chapter 1, only to announce, a few pages later, that "we now abandon this for its customary use, symbolizing wavelength"?

The author also takes the trouble to expose and explain theoretical difficulties which are too often ignored A good example of this is the section on "No Diffraction, by Cornu's Spiral", in which the limitations of this construction are pointed out, with the conclusion that "it affords the student an example of a typical theory in physics which has an impressive neatness, inspiring awe, which makes necessary compromises, requiring prudence, which is blemished by a lack of complete validity, requiring understanding"

At first glance the most distinctive feature of the book is the character of the illustrations These are in the style one associates with the author's well-known book on laboratory practice They have a freehand appearance, are pleasant to look at and are extremely clear, for example, the drawings in the section on double refraction, which is inherently a difficult subject to illustrate, are models of clarity What is even more important is that the drawings showing apparatus give one a good idea as to how it is actually constructed—too often one's first sight of the actual equipment comes as a shock after having seen only text-book illustrations It is only in some of the attempts to reproduce optical images by means of sketches that actual photographs might have been better

The book is described in the preface as being intended for an intermediate course in optics, taking one or two terms This is a considerable under-statement of the ground covered, and the book should be valuable for much more advanced students and also for general reference purposes It in fact covers most of the physical optics required for an honours degree in physics

The only real adverse criticism of this book concerns the price—£4—which is surely at least twice as much as most students would willingly pay for a single book This is to some extent offset by the seventeen so-called appendixes, which occupy nearly half the book, and are in effect a series of short monographs by specialists To quote the preface "these are intended to give the student the flavour of current activities and interests in our field" The topics covered in this way include, among other things, interferometers, apodization, Fourier transformations and interferometric spectroscopy, radiation detectors, micro-wave optics, wave theory of image formation, lens design, fibre optics and filters One of the appendixes supplies some of the mathematical background assumed in the rest of the book This is well done, and includes frequent attempts to make the student think—both by formal examples and by interjected questions such as "(why?)" or "(how do we know?)" after mathematical steps in the text J E Geake

BLOOD GROUP METHODS AND TECHNIQUES

Practical Blood Grouping

By Dr F Stratton and Dr P H Renton Pp xxiv+331+16 plates (Oxford Blackwell Scientific Publications, Springfield, Ill Charles C Thomas, Publisher, 1958) 42*s* net

OVER the past fifteen years mass grouping of blood donors and ante-natal cases has grown enormously, and of necessity special methods and techniques have been evolved to meet an entirely new situation

The authors of this book, faced with the alternatives of describing a multiplicity of methods, or confining themselves to those known and well tried in their own laboratory, have wisely chosen the latter

Not all would agree that the papain slide test offers substantial advantages over existing (and equally well-tried) techniques, for example, tube testing Even if some small advantage could be demonstrated, the disorganization which would follow a drastic change to a new technique would carry inherent dangers, probably outweighing any benefits likely to result

Nevertheless, it is always of value to study methods which have proved satisfactory over a number of years, and many pathologists engaged in this work will be most interested in a method which has satisfied such critical observers as the writers

In the section dealing with ante-natal grouping, the possible alternative to the current practice of ABO and Rh(D) screening, with the customary follow-up of the Rh(D) negatives, is attractive from the point of view of economy in laboratory working It might, however, be difficult to convince clinicians, and particularly obstetricians, that this economy at the expense of their advance knowledge of their patients' groups would be justified It is certain that they would argue, as is foreseen by the authors, that obstetric emergencies would not be so well covered

It would seem that the writers themselves have not adopted this possible alternative in their own practice, having doubtless explored the possibilities and the difficulties which it would entail

An interesting and informative chapter on cross-matching difficulties encountered in their own laboratory (p 237) was found to be slightly confusing For example, of the 2,967 cases involved the donor's blood was not of the ABO group as stated on the bottle in two cases

Without knowing the total number from which the 2,967 are selected the two wrongly labelled bottles may or may not represent a much higher proportion of error than is considered unavoidable in an earlier chapter

In any event, some explanation of how these two bottles escaped the rigid checks and cross-checks, described in detail in Chapter 7, where the combined manipulative and serological sources of error are calculated at 1 in 43,000, would be helpful

Two mistakes of this nature, picked up on cross-match, might represent a total of four such errors in the series, since bottles wrongly labelled O would escape detection by this final cross-matching check

Minor points, such as these, and the confusion in the description of the anti-U antibody (p 281) must not be allowed to detract from the value of this book The subsequent editions, which will assuredly be demanded, will provide opportunity for elucidation and correction

The bibliography is comprehensive and indicates the degree of care that has been taken in providing a manual which should appeal to pathologists, technicians and indeed to all engaged in blood transfusion work

R A ZEITLIN

SCIENCE AND THE HUMANITIES

History and Philosophy of Science

An Introduction By L W H Hull. Pp xi+340+16 plates (London and New York Longmans, Green and Co , Ltd , 1959) 25*s* net

“THIS is not a detailed history of science It tries to bridge the gap between science and the humanities by considering scientific ideas in a context of history and philosophy ” In these words the author describes the object of his work Few will deny the existence of the gap, or the need to bridge it, and a book of this nature should be welcomed, on one hand, by those whose training and background have led to an emphasis on technology, and on the other, by students of the humanities who seek to understand the vital contribution of science to human thought The general reader also will find the author's approach both interesting and stimulating , he anticipates the criticism that “most readers will, no doubt, find too little about some topics and too much about others” He points out that before the spread of evolutionary ideas the influence of biology seems scarcely comparable with that of mathematics and the physical sciences

The book opens with a review of ancient science covering three periods the first from the beginnings of science until the rise of Athens after the Persian wars , the second until the Macedonian conquests of the fourth century B C , the third period takes the Alexandrians as its theme This review is comprehensive in relation to the hundred pages allotted to it, and makes interesting and instructive reading Chapter 4 carries the story through the period of the Middle Ages, with some reference to Arabic contributions

In the two following chapters, celestial geometry and celestial mechanics are very adequately surveyed from the time of Copernicus to that of Newton With such fundamental changes in ideas concerning the universe, it is appropriate that a chapter is devoted to “Changes of Outlook and Method”, and this constitutes one of the most valuable parts of the book A separate chapter deals with other scientific developments in the sixteenth and seventeenth centuries, such as the phenomenon of light, and attention is directed to the philosophical thought of Berkeley and Hume

The chapter “The Nineteenth Century and Evolution' introduces the reader not only to Darwinian theory and its implications but also to its significance in the development of thought In an “Epilogue” which includes the theme of twentieth-century trends, the author gives a warning which it is to be hoped, in the interests of both science and the humanities, will not fall on deaf ears “It is urgently necessary to restore the unity of intellectual life Unless we do so, we shall soon lose what is best in Western civilization ”

H D ANTHONY

INDIAN PREHISTORY

The Pre-historic Background of Indian Culture

By D H Gordon (Sponsored by Bhulabhai Memorial Institute) Pp xi+199+32 plates (Bombay M D Desai, 1958 Distributed by N M Tripathi (Private), Ltd , 1958) Rs 20

UNTIL recent years the study of the archæology of the Indian peninsula has woefully lagged behind that of some other parts of the world Especially is this so in the case of its prehistory It is true that isolated finds of stone implements have been made from time to time during the past one hundred years—and in this connexion the name of Bruce Foote in Madras has an honoured place—but it is only recently that it has become possible to piece together an overall picture of the successive cultural phases in India, and even now the gaps in our knowledge are more than numerous The subject is complicated since India seldom presented a uniform picture Even in very early times the Madras area formed part of the vast Chelleo-Acheulean complex, while the northern regions belonged to another and distinct province which included the early stone-age cultures of Burma and south-east Asia. Most of the worthwhile investigations have, until recently, been undertaken by non-Indians, but nowadays highly trained investigators like Dr. Sankalia and his colleagues have come into the field and are making important explorations. But there is so much to be done in the field that there is little opportunity for these investigators to stand back, as it were, and give a general report of what has so far been pieced together of the ancient history of their fascinating land. It is here that Colonel Gordon steps in.

Gordon has served, travelled and explored in India for thirty-two years and himself has undertaken not a few investigations, and he knows as much about the rock-shelter paintings of the Central Provinces as any man alive. But in the volume under review he has set himself the task of attempting to see the archæology of India as a whole and to make available for students the latest ideas on the subject. Geographically, India is a large and varied country, and just as the cultures are not, and never have been, uniform throughout, so the climate differs in different areas and has differed greatly in past ages. A brief study of climate changes must necessarily be considered first, and then the earliest stone age cultures can come under review. The later stone age cultures are next dealt with, and here it must not be forgotten that in some regions these seem to have continued until quite a late date; indeed some of the Megalithic tombs and polished stone axes have been dated as late as the third century B.C. A chapter on the peasant potters of Makran, Baluchistan and Sind follows, and this naturally leads on to a discussion of the civilization of the Indus valley. Thanks to Sir John Marshall's work and the excavations at Mohenjo-Daro and other sites, a great deal has come to light of recent years, and this fascinating civilization has become comparatively well known. The period of invasions and the rock paintings and engravings are then dealt with, and in conclusion there are chapters on the 'Dark Age' stone and copper cultures, leading to a chapter which carries on the story to the threshold of history and to the use of iron.

Colonel Gordon has done his job well. It must not be expected that in one small volume the student will find detailed studies of the archæology of the whole of India. But the selections made are judicious and the result does give a connected picture of the past. There are a number of full-page illustrations at the end of the volume and plenty of maps, tables and text figures.

M. C. BURKITT

FLUID SYSTEMS

Chemical Engineering Practice.
Edited by Herbert W. Cremer and Trefor Davies. Vol. 6: Fluid Systems II. Pp. vii + 600 + xx. (London: Butterworths Scientific Publications; New York: Academic Press, Inc., 1958.) 95s.; 13.30 dollars.

THE latest volume in this series covers a very wide range of chemical engineering operations, although for convenience the editors have labelled the volume "Fluid Systems II". There are fifteen chapters covering gas absorption, fluidization, liquefaction and fractionation of gases, adsorption, leaching, crystallization, colloids, filtration, sublimation and the practice of evaporation. Dr. Norman and his colleagues from Manchester have written two chapters on the principles of gas absorption and the characteristics of packed-column absorption towers. The first chapter is excellent, not only for those in universities and technical colleges but also for all who are concerned with gas absorption. The second chapter, though good, lacks a little of the practical touch one would have liked. The chapter on evaporation practice by Mr. Watkins from King's College, London, assisted by Mr. Macmurray from Scott and Son and Mr. Forker from the Dupont Company, is very readable and covers the usual types of units. More attention might have been given to the actual size of units and some of the practical problems associated with operating evaporators would have been appreciated.

The chapters on fluidization by Dr. Botterell from Birmingham and Mr. Turner from British Petroleum are excellent, and will be looked at very much as indicating the position with this relatively new technique, which offers so much promise of further development. In the same way the chapters by Dr. Gardner of British Oxygen Co., Ltd., and by Mr. Pasteur of J. and E. Hall are welcomed as showing the real problems and successes of low-temperature technology. Low-temperature gas separation is still a new technique but most challenging as a technical process.

Prof. Donald has given an interesting account of leaching, including one or two references to history which are lacking from the other chapters. One is left with the idea that operations of such long standing are not yet carried out with very elegant equipment and there must be room for improvement here. The chapter on the principles of filtration is also written by Prof. Donald.

Dr. Mullin from University College, London, has written the chapters on crystallization, centrifuges, and colloid science. These are all difficult subjects and one would certainly have liked more on the practical difficulties of continuous crystallizers. We cannot learn from these chapters the physical size of units for definite capacities and there are many unresolved problems in the production of true regular crystals.

Mr. Salter, from Dorr-Oliver, and Mr. Hosking, from L. A. Mitchell, have given a clear statement of the variety of filters and the method of selection of equipment. Their section on accessories such as pumps and blowers for vacuum filters is a real attempt to size up these important auxiliaries. One cannot help feeling that some of these units have had their day and are a bit crude; some pruning of variety might have been suggested by these specialized authors.

This book enables one to see the range of processing problems which are now regarded as the province of the chemical engineer. It is not surprising that in his relatively short history there are many untidy edges to his work. Apart from selecting the right type of unit there is a definite degree of uncertainty as to the ability of the engineer to scale-up such plant satisfactorily.

The book will be welcomed particularly as it provides a discussion of the work in quite a number of fields which have not been adequately covered before in the British literature.

Mr. Cremer has written a foreword to the volume in which he refers to the untimely death of the former managing editor, Mr. Trevor Davies. Mr. S. B. Watkins, head of the Chemical Engineering Department at King's College, London, has taken up the work.

J. M. COULSON

Basic Electricity

(A Course of Training Developed for the United States Navy by Van Valkenburgh, Nooger and Neville, Inc Adapted to British and Commonwealth Usage by a Special Electronics Training Investigation Team of the Royal Electrical and Mechanical Engineers) Part 1 Pp vi+127 Part 2 Pp vi+121 Part 3 Pp vi+122 Part 4 Pp vi+104 Part 5 Pp vi+117 (New York The Brolet Press, London Technical Press, Ltd, 1959.) 12*s* 6*d* net per part, 55*s* net the set

THIS five-part course, aimed at training technicians rather than electrical engineers, is distinguished by the simple language of its text and its concentration on essentials It is illustrated to an extent that makes it (or at least the first two parts of it) qualify as a visual aid as well as a text-book The cartoon-like artistry is a little florid—the sort of thing one might associate with "Jane" but not with "Fighting Ships", and the going seems slow, by ordinary teaching standards, in the early stages It soon becomes evident what the authors are up to—using the same technique as the creators of the Li'l Abners and the purveyors of branded goods, to set up an image and attract a loyalty to it, the image being that of the electron I have no doubt that the early parts would be highly successful in bringing people who would not normally gain a great deal from the printed word to a really sound understanding of the fundamental principles, and simple circuits and meters The last three parts use the artist in a much more quantitative kind of way The usual work on alternating current, a c circuits, and electrical machinery is done with the minimum of algebra, but every important result is explained and illustrated with the help of vector diagrams and graphs These parts, in fact, are a very well-conceived text-book of the orthodox type, and contain some new ideas for expounding the more difficult points, which are never shirked Instructions for experiments are given, with a list of apparatus needed to work through them The really exacting part of instruction at this level is in making the initial contact with the pupil The originality and skill that have been lavished on the early stages of the course should ensure for it a very high contact potential G R NOAKES

The Strategy of Chemotherapy

Eighth Symposium of the Society for General Microbiology, held at the Royal Institution, London, April, 1958 Edited by S T Cowan and E Rowatt. Pp ix+360 (Cambridge At the University Press, 1958 Published for the Society for General Microbiology) 35*s* net

THIS symposium shows what a complex field of research has developed from Ehrlich's pioneer work on the use of specific substances to attack micro-organisms in the tissues without damage to the host The organizer invited contributors to suggest fresh methods of attack and the result was a series of papers of extreme diversity in approach, techniques and objectives They were given by the microbiologist, the pharmacologist, the biochemist and physical chemist, and include such fundamental conceptions as membrane penetration, bacterial cell-wall synthesis and energy-supplying reactions, wherein the research worker is endeavouring to discover some subtle difference in the components of host and parasite which may be exploited to the detriment of the latter At the other end of the scale are the frankly empirical mass methods used so successfully in the production of the antibiotics and other synthetic drugs, but without any fundamental explanation These random methods still offer probably the greatest chance for further production of new compounds and therefore have their place in the field of chemotherapy, but the symposium does emphasize the necessity for the combined operations of each type of research worker if chemotherapy is to have a logical basis of development and not be, as one worker defined it, dependent upon intelligent guesswork H BERRY

The Native Pinewoods of Scotland

By Prof H M Steven and A Carlisle Pp xvi+368+20 plates (Edinburgh and London Oliver and Boyd, Ltd, 1959) 63*s* net

THIS beautifully produced book will be a welcome occupant of the bookshelves of many students of Scottish history and natural history The subject-matter is both broader and narrower than the title might suggest—broader in so far as the authors discuss much relating to the general history of Scottish forests and to the relationships of pinewoods to woodland of other species, narrower in so far as some features of the pinewoods receive particularly detailed treatment

The authors trace the history of Scottish woodlands from the Pleistocene period onward through historic times, collating and summarizing an immense amount of evidence from geological, palynological and archæological sources which has never before been brought together They pass on via a very general ecological account of the pinewoods to a systematic description of all the known surviving examples of woods which are with reasonable certainty composed of naturally regenerated indigenous pine Carefully prepared maps accompany the descriptions, and show the exact distribution of pine and of other species of trees in the neighbourhood of the pinewoods This portion of the book is noteworthy for copious historical information which has been gathered together from estate records, early maps, accounts by travellers, etc An account of Dr Carlisle's study of the morphological variation of pine in Scotland concludes the book

A fine series of photographs illustrate the book I have noticed only one trivial misprint The book should form a valuable foundation for further ecological work in our western outposts of the European boreal conifer forest, which have so long attracted British naturalists E W JONES

South African Animal Life

Results of the Lund University Expedition in 1950–1951, Vol 5 Edited by Bertil Hanström, Per Brinck and Gustaf Rudebeck Pp 520 (Stockholm Almqvist and Wiksell, 1958) 75 Sw kr

VOLUME 5 of this series of publications contains accounts on Porifera, Crustacea, Diplopoda, Diptera, Hemiptera and Coleoptera Six chapters each on the Hemiptera and Coleoptera make up the bulk of this volume As in earlier volumes the taxonomic treatment is amplified by zoogeographical accounts, and frequently the general accounts are not restricted to the description of the Lund collections, but bring them into relationship with other material For an assessment of the scope and general merit of this series the reader is referred to an earlier article in this journal (*Nature*, 180, 56, 1957)

Inside the Living Cell

Some Secrets of Life By Dr J A V Butler Pp 174+16 plates (London George Allen and Unwin, Ltd , 1959) 21*s* net

DR J A V BUTLER'S former book, "Man is a Microcosm", was reviewed enthusiastically in these pages some years ago The scope of the present work is much wider, quite apart from the fact that many parts of the subject have advanced radically in the past few years

The author describes in straightforward language many of the great advances which have been made during the past ten years in our knowledge of the mechanisms which operate within living cells These include not only the ways in which food materials are taken and transformed into proteins, nucleic acids and other constituents, but also the way in which the ability to make all these is transmitted from generation to generation In these processes we come very near to the basic mechanisms of life itself In addition to his excellent account of the normal behaviour of cells the author discusses neoplasms and other abnormalities caused by ionizing radiations, those which seem to occur spontaneously and those which are caused by chemical carcinogens

Later in the book some abilities of specialized cells, such as those which form muscles and nerves, are dealt with, and an account is given of the immense structures which living cells achieve in the higher animals and finally in man

Altogether the reader is given some idea of what life has achieved, first, in reaching the level of the cell, and secondly, in elaborating great assemblies of cells in the higher forms of life Finally, the author discusses the causes and significances of ageing and death, and the meaning of life in the world of atoms

Throughout, the work is informed by the original work and thought of the author The book is beautifully produced in every way The illustrations are particularly good and include photomicrographs such as those by D A Sholl of nerve cells in the visual cortex, and by R W G Wyckoff of bacteriophage The book can be recommended warmly to many classes of reader Most of it should appeal to the educated adult and it will be invaluable for the general reading of a good science sixth former, or university undergraduate W L SUMNER

Organic Syntheses

An Annual publication of Satisfactory Methods for the Preparation of Organic Chemicals, Vol 37, 1957 Edited by James Cason Pp vii + 109 Vol 38, 1958 Edited by John C Sheehan Pp vii + 120 (New York John Wiley and Sons, Inc , London Chapman and Hall, Ltd) Each 32*s* net

AMONG the 32 compounds for which preparative methods are described in Vol 37 are benzofurazan oxide, *trans*-2-dodecenoic acid,, glutaric acid and glutarimide, norbornylene, parabanic acid, and *ar*-tetrahydro-α-naphthol , and the 31 preparations of Vol 38 include diphenylacetaldehyde, hendecanedioic acid and several related compounds, monobenzal- and monobromo-pentaerythritol, monovinylacetylene, *trans*-stilbene oxide, and 2-vinylthiophen Each volume has a cumulative index extending back to Vol 30 Four enclosed leaflets direct attention to explosions that have been experienced in preparing ethyl azodicarboxylate, methoxyacetylene, and *o*-toluamide, and in storing *p*-tolylsulphonylmethylnitrosamide JOHN READ

Trends in Birth Rates in the United States since 1870

By Bernard Okun (The Johns Hopkins University Studies in Historical and Political Science, Series 76, No 1) Pp 203 (Baltimore, Md The Johns Hopkins Press , London · Oxford University Press, 1958) 3 50 dollars , 28*s*

THIS monograph consists of three essays The first two discuss the secular trend of the declining birth-rate in the White and Negro population of the United States, respectively The method used is an analysis of fertility indices (the ratio of children to the total population, and the ratio of children to women of reproductive age) in different States of the U S A The discussion will be of interest mainly to the specialist in demography, and adds little to what is already available in the monograph by Grabill, Kiser and Whelpton, who have surveyed the material in much greater detail The third essay, however, is of more general interest Here Dr Okun surveys the hypotheses and approaches used in explaining birth-rate trends, and attempts a classification and an assessment of the methods that can be used to test the hypotheses No very definite conclusions emerge, but the essay is a useful summary

The Structure of Glass

Proceedings of a Conference held at Leningrad, November 23–27, 1953 Translated from the Russian by E B Uvaroc Pp ii+295 (New York Consultants Bureau, Inc , 1958) 20 dollars

THIS translation was sponsored by the Glass Division of the American Ceramic Society and the National Science Foundation with the expressed object of providing a general look at the status of glass science in the U S S R , and admirably does it fulfil its purpose The fact that this conference was attended by more than 500 delegates from twenty-eight towns of the Soviet Union is itself impressive, and conveys immediately an idea of the large scale on which research in this field is being conducted

As a report of a conference the volume is excellent , the printed discussion is particularly lively, and occupies 70 pages , 42 papers were communicated to the conference and these account for 228 pages of the volume Remembering that the conference took place five years ago it would appear that at that time there was no great difference between the topics being discussed in the U S S R and in Western circles

It would be easy to dismiss the discussion as being concerned too much with semantics and to criticize some of the ideas put forward However, examples of similar ideas and arguments are well sprinkled through the literature The great argument of the conference was on the rival merits of the 'random network' theory of glass structure and the 'crystallite' theory The proponents of the crystallite theory attacked their opponents on the ground that the randomness was not complete, while their own definition of 'crystallite' was hedged by sufficient qualifications to make it clear that the majority of them did not mean that term to imply anything that could properly be described as a crystal

Perhaps the fairest summing-up is that here there is realization that the network theory of glass is only a first approximation—a view which is receiving increasing emphasis at the present time

The translation was well worth while, and all interested in the physics and chemistry of glasses will enjoy reading the book R W DOUGLAS

LIBERTY IN AN AGE OF SCIENCE*

By Sir SOLLY ZUCKERMAN, C.B., F.R.S.

Department of Anatomy, University of Birmingham Medical School, Birmingham

IF, two or three decades ago, one had spoken of science and liberty in the same breath, the emphasis would have been different from my present theme. That period was the era in which the social function of science was a central issue of debate, and it culminated in the almost total mobilization of the scientific forces of our two countries during the Second World War. This War was the turning point. Where previously scientists were seen, according to the interests of the observer, either as dedicated scholars, or as the source of invention, or as the technical guardians of the social services on which an urban civilization depends, to-day they also appear in a number of new guises—as the backbone of national defence; as pioneers of outer space; and even as the counsellors of presidents and prime ministers.

The world has come not only to recognize but also to insist that science has a social function; but, not all the world. There have always been those who have questioned whether the democratic way of life, and a life of liberty, can survive the stresses of rapid economic growth; and as the hazards of our century mount, their numbers are being reinforced by others who are fearful lest all society becomes a victim of the forces that have been unleashed in our present scientific age. "The scientists think they are God," one exclaims; "they want to remake the universe; and we pay the price for their mad ambition."

This is no lonely voice, and it is one that has been heard before. Long before the days of artificial Earth satellites, long before the era of nuclear weapons, George Gissing wrote: "I hate and fear science because of my conviction that for a long time to come, if not for ever, it will be the remorseless enemy of mankind; . . . I see it bringing a time of vast conflicts, which will pale into insignificance the thousand wars of old and, as likely as not, will overwhelm all the laborious advances of mankind in blood-drenched chaos."

But what science is this that is the enemy of mankind? Surely not the pure thought or theory which enhances man's understanding? It is well to consider out of what confusion it is that science presents this ominous look.

The cultivation of science, by which we mean the quest for new natural knowledge through controlled and reproducible observation, can be treated as an endeavour which is either personal and private, or social and public. But however pure or personal may be the object of acquiring a scientific understanding of the universe in which we have our being, science inevitably becomes social or public not only because there can be no awareness of the existence of a new scientific idea until it is communicated from one person to another, but also because pure science frequently turns out to be basic to some practical development—to some piece of applied science—or to some convention of thought, which then starts transforming the environment within which it was distilled. So it is that pure science and applied science have progressed hand-in-hand over the years, the pure fertilizing the applied with ideas, and the applied often providing the pure with the physical apparatus to help in the next intellectual leap forward.

This process has been a major factor in the progressive replacement of superstition by rational theory. And as Condorcet—that great French scientist of the latter half of the eighteenth century who was so powerful a protagonist of human dignity and freedom—wrote: "The progress of the sciences ensures the progress of the art of education which in turn advances that of the sciences"—a reciprocal operation which he did not exaggerate by describing "as one of the most powerful and active causes working for the perfection of mankind".

Man's evolution has also meant the continuous transformation of his social institutions through the directed application of pure scientific knowledge. We talk to-day of living in a new age of science, of a world in the throes of a new scientific revolution; but there is nothing new about this revolution except its speed and its greater hazards. Science has always revolutionized society, ever since some basic discoveries in animal husbandry and crop cultivation made it possible for nomadic life to give way—ten to twenty thousand years ago—to permanent village settlements, and so to the diversification of labour and the beginning of trade.

The transformation of society by scientific discovery and application has continued ever since, sometimes so slowly that decades pass before the historical record reveals much change, sometimes as at present, with ever-mounting force. While it could be argued that the technical advances of the past ten to twenty years transcend those of the rest of human history; that the speed with which new discoveries are disseminated and applied is now unprecedented; that the political and economic consequences of all this scientific activity will prove far more profound than those which resulted from past epochs of discovery; there is nevertheless no immediate reason to suppose that the social process which is involved in to-day's scientific revolution is different in kind from what was entailed in previous phases of rapid change.

If we are to understand the confused position in which the layman and the scientist now stand in relation to each other, we need therefore to examine certain features which characterize the growth of scientific knowledge, and also some which relate to its present impact on social affairs.

What, first, do we mean by the need for academic freedom as it applies to the pure scientist? One means not only the freedom to investigate those problems which one seeks oneself, but also the fact that significant advances in scientific knowledge cannot be ordered by decree. Every act of creation requires its special freedom. While our theories of thermodynamics, of relativity, or of natural selection, undoubtedly had their antecedent relations, no one could have predicted, before it actually occurred, if, and how, and when any of these major advances in our scientific understanding was to have taken place Nor would it be possible to force a scientist to make this or that specified discovery For example, genius though he was, no one could have prevailed upon Charles Darwin, say, in 1830 when he was twenty years old, to anticipate the basic genetic law revealed by Gregor Mendel thirty-five years later One can employ special measures to encourage this or that branch of science One can provide the conditions in which pure science flourishes, by multiplying the opportunities which make it possible—the universities, the laboratories, the freedom from other responsibilities But having done these things, one can only then wait to see what emerges One cannot in advance specify the shape and content, or determine the possible impact of what is not yet known.

---

* Substance of the address delivered at the Sixty-fifth Commencement Exercises of the California Institute of Technology on June 12.

Being unpredictable, it follows that the untrammelled emergence of new scientific ideas is not compatible with any restraint on the liberty of the scientist to roam where his fancy leads Indeed, once the growth of any set of scientific ideas becomes constrained, it stands in danger of becoming obstructive dogma A valid scientific hypothesis is never more than the best statement which, for the moment, can be made of the relations of the matters to which it refers, and should be swept away as soon as a better one emerges

The growth of science thus necessitates freedom, even the freedom to be revolutionary How then is stability to be achieved in a world in which science has so great an impact ? How does science become, as it has often been described, the servant and the handmaiden of freedom ?

One's immediate answer is that since economic and military power are to-day proportional to the degree with which scientific knowledge is exploited, science is the defender of the ideal of freedom on which Western democracy rests In a more particular sense, as many have pointed out before, the applications of science have also provided the apparatus which has made central government powerful

But surely science is in these respects no more the servant of the democracies than of the authoritarian regimes poised against them, and of the philosophical and political concepts on which they, in turn, are based In a world of conflicting power, science is both the arsenal and instrument of power—but science *qua* science is always a neutral arsenal and a neutral instrument

We cannot invest pure scientific knowledge with any inherent moral direction That is imparted by the way science is used, and we can be certain, therefore, that all sides in the present world struggle will use science and technology in the achievement of their respective national aims , and also in whatever efforts they may make to narrow the ever-widening gap between the developed and under-developed territories of the world

My first main point, therefore, is that while the growth of fundamental scientific knowledge necessitates complete freedom from restraint, science is not uniquely associated with the preservation of freedom either in the personal or social sphere

But there is a deeper issue underlying the relation of science and freedom Let me first define the sense that I propose attaching to the concept of freedom or liberty, which both in isolation, and as the ideal which animates democracy, has always been a major concern of philosophical discussion

By freedom I mean here the liberty an individual enjoys after the infinite number of degrees of freedom which are open to him in the abstract have been reduced by, say, the give-and-take of social life, still leaving a vast area of choice within which he could either engage in, or desist from, any particular activity It was essentially in this sense that the great utilitarians of the industrial revolution—Bentham, John Stuart Mill and others who joined them in the battle for justice—conceived of freedom in the ideal society—a society which is governed by common consent for the common good , in which the greatest number enjoy the greatest happiness , in which there is equality of suffrage, and in theory, at least, in educational and economic opportunity , and in which laws and institutions, regulating the behaviour of individuals, are there because the unlimited exercise of one man's liberty would inevitably impose restrictions on that of his fellows

It is essentially in this social sense, however 'negative' it may be, that liberty is implied in the proposition that science is its handmaiden Science may, of course, well be the handmaiden of equality in the economic sphere, given, of course, the right political institutions But is the proposition true in the philosophical sense of the term 'liberty', whether in relation to the concept to which I am directing my observations or to any other idea of liberty which philosophers have examined ? Can it be true of the actual environment within which we exercise our freedom—an environment which is not some unreal stratosphere peopled either by abstract shadows of human beings or of social groups ? Surely our social environment is a real one which is constantly being transformed by new scientific ideas, and by the application and practical development of these ideas This transformation constitutes more than a process whereby men are conditioned in their thoughts and actions Whenever some major development is pursued, for example, the development of machines based on steam, it means that some other path that potentially might have been followed was not followed A material civilization of motor-cars, of radio, of synthetic fibres, of nuclear power is not necessarily the only form a material civilization might have taken But now that it has taken that shape, it helps define for us the content and boundaries of the area within which we exercise our freedom

Liberty, in the sense I am using the term (and I believe to most political philosophers), means the power to act freely within the compass of the institutions which a people may set up in the exercise of their sovereign power, which implies their right to act as they think best as a collective body and which, according to legal theory, "is not restrained in any way except by the limitations inherent in human nature" It is irrelevant here that the exercise of democracy may not infrequently depart from its ideals , or that the institutions which had to be set up to preserve the hard-won freedom of modern times may themselves have eroded the principles they were meant to preserve The point I wish to make is that science, through its practical impact, is to an increasing extent, almost to a dominant extent, determining the way the presumedly uninhibited sovereign power expresses itself Because of its achievements in eliminating disease and alleviating pain, through the food and wealth it has brought, most people to-day prefer to regulate their lives in accordance with scientific discovery rather than in any other way In that sense they are prepared to constrain their abstract liberties in accordance with what science unfolds, and the riches it brings Is the choice, we may ask, conscious ? Can we know for what it is we are opting ? Hobbes, like other philosophers, found liberty consistent with necessity Is liberty truly consistent with necessity, when necessity is determined by science ? Is the sovereign power consciously deciding to develop this or that scientific discovery, and so to determine social development in this or that direction ? Or is it merely adapting itself as best it can to what comes out of Pandora's scientific box ?

The answer to any of these questions is inevitably bound up both with the constraints and unpredictability of any new major scientific advance Of course, there are always certain fields of science which are more popular and better supported than others Scientific knowledge never develops evenly over the whole potential field of knowledge But in so far as scientific activity is in general confined by past discovery to certain areas, so is our abstract liberty, in effect, constrained Furthermore, in any field of science, several alternative courses of action might be pursued in search for a solution to a problem In choosing any one of them, the research worker may deny himself, and others, the opportunity of pursuing another There is also the increasing complexity of the scientific knowledge which is now being transformed into new remedies, new chemicals, weapons-systems, and so on The facts which these days transform our lives become more and more difficult to comprehend, and on occasion are still not fully decided when they are applied If this were not so, would there still be debate—I choose the most urgent example of all—about the hazards associated with radioactive fall-out ?

Above all is the fact that the nature and magnitude of potential discovery cannot be defined in advance , any more than can its impact on our social lives As de Tocqueville wrote "We entrust ourselves to the future, an enlightened and impartial judge—but one who sits, alas, always too late "

Faraday, Hertz, Curie—what could they have known of the ultimate uses to which their discoveries would be put in the field of electric power, radio and nuclear energy , or of the social and political consequences of their uses We ourselves, years later, cannot tell what these consequences will be Can we, to refer to just one more vital question out of many new ones this scientific age is generating, commit ourselves now to more than arbitrary views of the possible political consequences of the elimination of disease and of its complementary change, the explosive growth of population in so many areas of the globe ?

Science has created wealth , it has helped in the struggle for freedom from economic exploitation , it has redistributed power But in doing these things, as it widens the area of material choice, it circumscribes and determines the environment in which we exercise our abstract liberties That is my second point Itself demanding freedom, and revolutionary in its ways, science is now determining, in an increasingly unpredictable way, the main issues about which we, as citizens, exercise our freedom of choice Can there be much more than a fictional verity to the abstract idea that an area exists within which men can enjoy the capacity of unconditioned or untrammelled choice ?

Democracy was man's answer to tyranny and exploitation The only form of exploitation it will never help overcome is the coercion of new knowledge, which by guiding our social lives into certain channels, limits advance in other directions , the new knowledge which focuses the interests of humanity on goals which cannot be properly charted until they have been achieved To the philosopher, as I have said, ultimate limitations on the freedom of the individual are set by the inexorable laws of Nature To the scientist, the limitations are set by the particular laws of Nature man himself discovers, out of a potential infinity of such laws, and from the use to which he puts these laws

Up to now we have been able to claim that the applications of science have increased the sum total of human happiness But to-day we stand at a cross-road The process of applying scientific knowledge is as endless as is the prospect of gathering new knowledge, and the basic scientist is responsible for only the beginning of the cycle of activity which creates a demand for the application of his discoveries Industrialization has established itself as the one sure cure for poverty in a world the bulk of the population of which still lives by subsistence farming , and history as yet gives no example of any but small communities which have voluntarily turned their backs on higher material standards of living Instead, a uniformity of desire and demand is generated for the so-called good things of life as the one world discovers how the other lives, and what it itself lacks Obviously we cannot say that the economic history of the West will be recapitulated as industrialization spreads, and as the chains of the past are broken in distant parts of the world But we can be all but certain that neither the needy nor the rich will allow the process of applying the fruits of scientific knowledge to stop, either in the national or the international frame In this process means become ends, because as new ways of doing things are discovered, they transform the things being done, and so their purpose In these days it is only in theory that one chooses weapons and tactics to achieve a strategy In fact, weapons often end by determining strategy—and sometimes the purpose behind the strategy

In my view it is against this force of scientific application that the Gissings of to-day rail—not against science as such , and it is this force which could constrain our democratic liberties, and which, if we ceased being vigilant, could even constrain the liberty of pure and basic science—and by so doing paradoxically destroy itself

Ideally we think that democracy to-day means government by the representatives of the people by consent of the people But many to-day also feel that the sovereign power, the people, has through a process of negative democracy, abrogated its rights to a power-*élite*, to a bureaucracy, to what-you-will, which is consciously determining the directions we follow This, it seems to me, is again too simple The element of the unknown in government increases with every step we are now taking to apply the fruits of science If sovereign power is being abrogated, it is less to some governing body, however formed , and more and more to a process of applying scientific knowledge without any real possibility of determining its final consequences Neither the voice of the majority, nor those through which it is expressed, can proclaim the precise lines of the future

Where do scientists stand, as ordinary citizens, in this process whereby the application of the fruits of their discoveries can become a potential prison for our abstract liberties? It is argued that because of their special knowledge scientists can be aware of the danger and promise arising from their discoveries, and that therefore they have a special responsibility in relation to the most pressing problems of our time. I should agree with this, if it meant no more than that scientists are better able to appreciate the scientific facts. For how can the scientist as such, who is not responsible for its application, accept the responsibility for predicting some vast social transformation that might result from what seems an innocent observation at the time it is made?

But I should agree all the more if one coupled with this view of the scientist's responsibility the thought that in the problem of preserving our liberties lies the most important reason for regarding an education in science as constituting to-day an essential part of an education in the humanities. For if an understanding of social and political purpose is one of the aims of the liberal arts, then that aim cannot be realized until their scope is widened to embrace a proper understanding of the scientific knowledge the application of which is now so rapidly transforming our intellectual and material environment.

Science, technology and humanism seem to have assumed that order of importance in the determination of our affairs. I do not know how it is in the United States, but over the post-war years the changes which the tacit application of science and technology have occasioned in Great Britain seem far more profound than any that have been brought about through the overt discussion of social values or social goals. If this kind of thing is happening, can the humanities continue as a potent educational discipline without encompassing an understanding of the social forces which derive from the application of the natural sciences? Scientific literacy, we are told in a recently issued report on education, will need to be far more widespread than it is "if we are to solve the problems of this age". Undoubtedly this is needed, but alone it is not a sufficient condition to ensure the solution of our problems—for here I agree with Aldous Huxley that "higher education is not necessarily a guarantee of higher virtue or higher political wisdom". What we most need to learn is that in the major scientific matters which now affect human destiny, one cannot safely take decisions for to-day unless we realize that those same decisions determine the future. This realization may not lead to the right decisions, but it might help obviate some of the worse.

SATELLITE OBSERVATIONS OF SOLAR COSMIC RAYS

By PAMELA ROTHWELL and CARL McILWAIN
State University of Iowa, Iowa City

On three occasions during August 1958, large increases in the intensity of charged particles outside the Van Allen radiation zones were detected by the *Explorer IV* satellite 1958 epsilon, at high magnetic latitudes and rather low satellite altitudes (270–650 km.), where the Geiger tubes carried in the satellite normally count only cosmic rays. Figs. 1, 2 and 3 show that the charged particle intensity in both counters increased sharply with magnetic latitude, above about 60°, on August 16–17, August 23–24 and August 26–27. (We have defined 'magnetic latitude', λ_{dip} from the magnetic dip angle δ at the point of observation, through the dipole relation $2 \tan \lambda_{\text{dip}} = \tan \delta$.) Different symbols have been used for each satellite pass on any one day, recorded at the microlock station in Van Buren, Maine, in the geographical longitude range (95° W.–45° W.). The time-interval for each pass (usually about 5 min. duration) is given, and each point has been characterized by the altitude in kilometres at which the observation was made. The charged particle detectors in the satellite have been described in detail elsewhere by Van Allen *et al.*[1] The two Geiger counters (one shielded with 1.6 gm./cm.^{2} lead, and the other unshielded except by the satellite hull) could detect protons of energies greater than 40 MeV. and 30 MeV., respectively, and electrons of energies greater than about 5 MeV. and 3 MeV. The omnidirectional geometric factors ranged from 0.140 cm.^{2} to 0.823 cm.^{2} in the shielded counter, and from 0.140 cm.^{2} to 0.705 cm.^{2} in the unshielded counter. Table 1 gives the upper and lower limits to the omnidirectional fluxes of particles which would produce the highest observed counting rates in (*a*) the unshielded counter

Table 1

Date August 1958	Time of satellite pass (U.T.)	(*a*) Flux through unshielded Geiger counter (particles/cm.^{2}/sec.)	(*b*) Flux through shielded counter (particles/cm.^{2}/sec.)	(*c*) Ratio of counting rates unshielded/shielded	(*d*) $E_{\min}$ (MeV.)	(*e*) $E_{\max}$ (MeV.)	(*f*) Elapsed time after 3 + solar flares (hr.)
16	11.17–11.19	$86 > J_{0u} > 17$	$78 > J_{0s} > 13$	1.1 ± 0.3	~ 90	~ 200	6.8
16	13.11–13.15	$193 > J_{0u} > 38$	$179 > J_{0s} > 30$	1.1 ± 0.2	~ 60	~ 200	8.7
17	11.01–11.06	$240 > J_{0u} > 48$	$86 > J_{0s} > 14$	2.8 ± 0.3	~ 90	~ 200	30.5
17	12.56–13.00	$121 > J_{0u} > 24$	$43 > J_{0s} > 7$	2.8 ± 0.5	~ 60	~ 200	32.4
23	09.22–09.30	$577 > J_{0u} > 115$	$193 > J_{0s} > 33$	3.0 ± 0.2	~ 90	~ 250	19.1
23	11.14–11.23	$445 > J_{0u} > 88$	$150 > J_{0s} > 25$	2.9 ± 0.2	~ 35	~ 250	21.0
24	10.59–11.05	$140 > J_{0u} > 28$	$37 > J_{0s} > 6$	3.8 ± 0.5	~ 35	~ 250	43.8
26	08.26–08.34	$1{,}010 > J_{0u} > 200$	$465 > J_{0s} > 79$	2.2 ± 0.1	~ 85	~ 350	8.4
26	10.22–10.28	$1{,}300 > J_{0u} > 265$	$515 > J_{0s} > 88$	2.5 ± 0.1	~ 55	~ 350	10.3
27	08.06–08.15	$143 > J_{0u} > 28$	$46 > J_{0s} > 7$	3.1 ± 0.5	~ 85	—	32.0
27	10.04–10.08	$132 > J_{0u} > 26$	$50 > J_{0s} > 8$	2.6 ± 0.5	~ 55	~ 350	34.0

Fig 3

(J_{0u}), (*b*) the shielded counter (J_{0s}), and (*c*) the ratio of these counting rates (unshielded/shielded) at each satellite pass on which an increase in intensity was observed The cut-off energies for protons, at (*d*) the highest magnetic latitude on each pass ($E_{\min}$) and (*e*) the lowest latitude at which counting rates in excess of the cosmic ray rate were recorded ($E_{\max}$), are estimated from the local values of the Earth's magnetic field[2]

The particle fluxes are at least one or two orders of magnitude greater than the normal cosmic ray flux It seems unlikely that these intensity increases are due to soft particles from the outer Van Allen radiation zone, because

(*a*) *Explorer IV* cuts through the outer zone (as observed with the Geiger counters) at about 56° magnetic latitude, that is, farther south than the intensity increases reported here

(*b*) The ratio of counting rates between the unshielded and shielded Geiger counters in the outer zone is typically, about 30 or 40 to one, in contrast to the comparable counting rates observed in both counters at the higher latitudes

The ratios unshielded/shielded are reasonably consistent with the hypothesis that the charged particles are protons the energies of which lie between $E_{\min}$ and $E_{\max}$ The wide limits placed on the estimated fluxes are due to the uncertainty in the absolute geometric factor for the counters in the proton energy-range 30–100 MeV

We suggest that the intensity increases are in fact due to solar protons, associated with the large solar flares which occurred at 0432 U T on August 16, 1417 U T on August 22, and 0005 U T on August 26[3] Strong support for this suggestion is provided by measurements made from balloons and with riometers during this period

(1) Anderson[4] and Winckler *et al.*[5] measured an increase in charged particle intensity at balloon altitudes above Churchill, Canada (magnetic latitude 77°), and Fairbanks, Alaska (magnetic latitude 64°), on August 22 and 23, and have identified the particles as solar protons of energies up to a few hundred MeV. It is almost certain that the satellite has recorded the same event. (The increased intensity was not observed until August 23 because there was no pass over Van Buren after 1100 U.T. on August 22.) Anderson *et al.*[6] deduce a differential number energy spectrum $n(E)dE = K(t)E^{(-5 \pm 0.2)}dE$ (where t is the elapsed time after the solar flare) for the solar protons in the energy-range 100–400 MeV. At 1115 U.T. on August 23 they estimate that the flux of particles with energies greater than 100 MeV was about 1·5/cm.²/sec. Intensities observed from the satellite at that time suggest that a spectrum of this form may well extend down to about 30 MeV.

(2) Leinbach and Reid[7] have suggested recently that the absorption of cosmic radio noise, measured with riometers following large solar flares, is due to ionization of the upper atmosphere by solar protons. H. Leinbach (private communication) and Hultquist and Ortner[8] have observed three such events, commencing August 16, August 22 and August 26, in the riometers at Thule (Greenland), Fairbanks (Alaska) and Kiruna (Sweden). Absorption effects of this type occurred on twelve other occasions, between July 1, 1957, and September 30, 1958 (H. Leinbach, private communication).

During the period August 16–27 no increase in intensity was observed in the Canadian cosmic-ray neutron monitors at Resolute, Churchill, Sulphur Mountain and Deep River[9] at magnetic latitudes of 88°, 77°, 61° and 62°, respectively, but it is not surprising that protons with a steep number-energy spectrum and maximum energies of a few hundred MeV produced no detectable effects near sea-level.

The ratio of the maximum counting rates in the two counters increased significantly during each event. This suggests that either (*a*) the shape of the energy spectrum of the solar protons changes, and relatively more low-energy particles arrive at later times; or (*b*) that some particles with energies below the usual magnetic cut-off energy can arrive at a given location later in the event.

Freier *et al.*[10] have, in fact, reported that protons with energies below the usual measured cut-off were found at balloon altitudes over Minnesota on March 26, 1958, three days after a large solar flare, and at the time of a magnetic storm. When the Earth's field is disturbed, some charged particles can probably be admitted to regions normally 'forbidden' to them, and particles with energies below the normal cut-off may arrive at a given latitude during, and perhaps for some time after, the disturbance. During the period August 16–27 'sudden commencements' occurred at 0622 August 17, 0228 August 22, 0140 August 24, and 0303 August 27[11]. The lowest ratios unshielded/shielded occurred on August 16 before this period of magnetic activity.

There is now evidence from several sources which strongly suggests that solar protons with energies up to a few hundred MeV quite frequently bombard the upper atmosphere at high latitudes for some days following a large solar flare. The five widely observed, extraordinary increases in cosmic-ray intensity near sea-level which have occurred during the past twenty years of continuous observation are probably unusually energetic examples of a common solar phenomenon, namely, the acceleration and ejection of protons with energies approaching those of galactic cosmic-ray particles.

We should like to thank Prof. J. A. Van Allen and Dr. K. A. Anderson for many interesting discussions. This work has been assisted by the U.S. International Geophysical Year project 32.1 of the National Academy of Sciences, the U.S. Army Ordnance Department, the Office of Naval Research, and the Atomic Energy Commission.

A BORE-HOLE TO THE EARTH'S MANTLE: AMSOC'S MOHOLE

By GORDON LILL and WILLARD BASCOM

AMSOC Committee, National Academy of Sciences—National Research Council, Washington, D.C.

MAN'S knowledge of the interior of the Earth has been largely obtained by indirect methods, and although a great deal is now known about the qualities that subterranean materials must possess, numerous uncertainties remain. There is now a project under way, sponsored by the AMSOC Committee of the U.S. National Academy of Sciences to obtain corroborative evidence about the nature of the interior of the Earth by the direct method of drilling a hole completely through the oceanic crust to obtain samples of the mantle. Since the boundary between the crust and mantle is known as the 'Moho' (after Prof. A. Mohorovičić of Yugoslavia, who first described the seismic discontinuity there) it seemed reasonable to contract the project name to 'Mohole'.

The American Miscellaneous Society, founded in 1952 as a whimsical reproof of scientific societies which are sometimes too specific for their own good, uses its cable address, AMSOC, in the alphabetical world of Washington. It has no formal members, officers, by-laws or publications; and there is a bent towards geophysics.

On the subject of drilling through the crust of the Earth, however, the AMSOC group has been formally organized so that it can receive funds from the U S National Science Foundation The original members of the Committee were Gordon Lill (chairman), Prof Maurice Ewing, Dr William Heroy, Prof Harry Hess, Dr Harry Ladd, Dr Arthur Maxwell, Prof Walter Munk, Prof Roger Revelle, Dr William Rubey, Dr Joshua Tracey and Willard Bascom (technical director)

The Mohole project in more or less its present form was born at a breakfast at Prof Munk's house in California, at which he led the conversation on the need for a geophysical analogue for the space exploration programme The suggestion of Dr Frank Eastabrook, made in *Science* (October 1956) for the digging of a "Geophysical research shaft", had set forth the principal scientific advantages of direct sampling But AMSOC, unaware at the time of that suggestion, proposed a deep drilling project

The following September, in Toronto, at the meeting of the International Union of Geodesy and Geophysics, a resolution was passed "urging the nations of the world to study the feasibility and cost of an attempt to drill to the Mohorovičić discontinuity at a place where it approaches the surface" A hole 10–15 km deep on an oceanic island was suggested The sponsors were Harry Hess, Roger Revelle and T F Gaskell

The question of the structure and material of the interior of the Earth is a puzzle which has long challenged the mind of man In all major aspects the most acceptable present hypothesis holds together very well This is remarkable, for it requires that there be reasonable agreement between at least eight sub-sciences, all of which make indirect measurements Studies of astronomy, meteorites, volcanoes, geological structure, gravity, seismic waves, the magnetic field, and heat flow each contribute to the total knowledge

If one assumes that meteorites are the wreckage of a planet similar to the Earth and that the rocks spewed out by volcanoes (the seismic precursors of which begin well below the Mohorovičić discontinuity) contain samples of mantle material, then we already have samples of the deep rocks Moreover, Harry Hess believes that mantle rock actually outcrops (at St Paul's Rocks in the mid-Atlantic, in Japan and in California) Astronomical observations give the total mass, the average density and the moment of inertia of the Earth

But in the main, evidence about the interior of the Earth has come from earthquake waves By the combination of tedious computation and great skill, seismologists have worked out characteristics of the planet which keep within the limits set by the other evidence

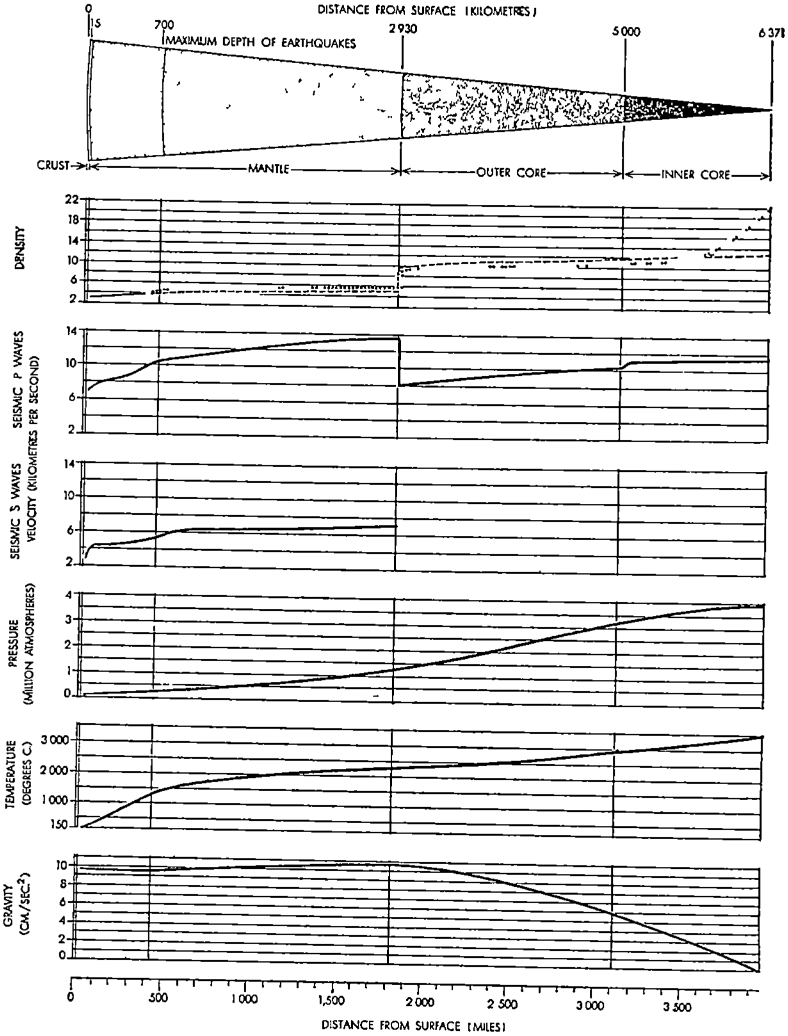

Fig 1 The interior of the Earth

The hypothesis of inner and outer cores surrounded by a thick mantle and capped with a thin crust has stood the tests of many years, now the problem is to refine the information and to obtain evidence which cannot come from further advances in seismology The composition of the mantle, which represents about 85 per cent of the volume of the Earth, is the principal problem of geophysics to-day, for although a lot is known about it, uncertainties remain (Fig 1)

The exact mineralogical and rock composition, the density, strength, temperature, the amount of radioactivity, the thermal and electrical conductivity—all these will contribute immeasurably to the understanding of the Earth and its origin Moreover, they will serve to enhance the value of the indirect geophysical measurements Finally, some new and entirely unexpected piece of evidence may be unearthed that will cause science to revise substantially its concept of the Earth

The crust is closer and easier to study than the interior, but even so it is more controversial Generally it is agreed that continents represent relatively thick blocks of andesitic rocks, and that ocean basins are composed of much thinner basaltic rocks—the average thicknesses being about 30 km.

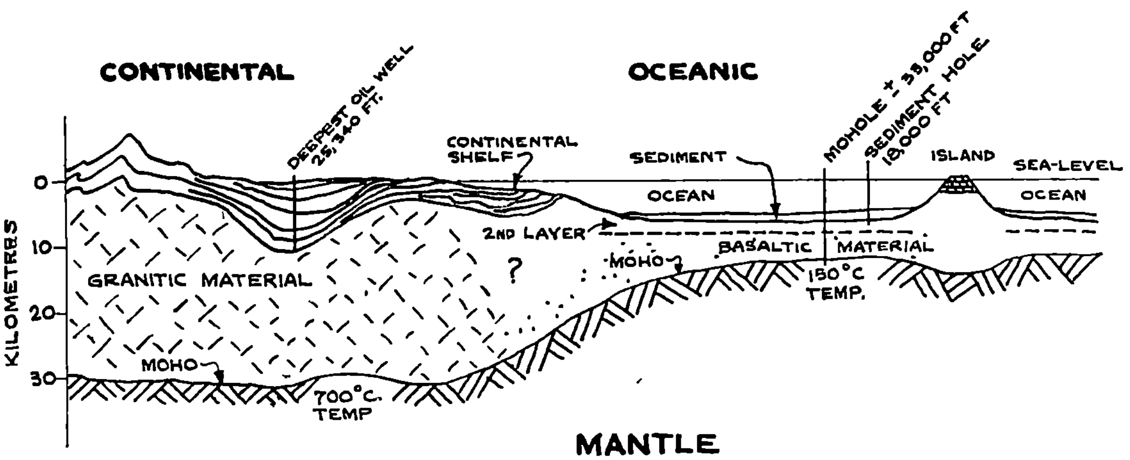

Fig 2 The crust of the Earth

and 10 km respectively The crust seems to act as though it is floating on viscous plastic mantle material, however, the response time is long, and certain anomalous areas not in isostatic equilibrium complicate the problem The Moho, which defines the boundary between crust and mantle, is recognized by an abrupt increase in the velocity of seismic waves—from about 7 0 km /sec to 8 2 km /sec

As the Earth developed, the water which reached its surface naturally ran downhill and covered the lower, thinner basaltic material, forming an ocean

The composition of the oceanic crust is studied by sea-going seismologists who use pairs of ships—one setting off explosions, the other listening In this way it has been discovered that beneath much of the ocean there are three main layers of material (1) the soft sediments, (2) the 'second layer', and (3) the 'third layer' (Fig 2)

The soft sediments of the deep sea floor (red clays and calcareous oozes) have been repeatedly sampled with corers which have penetrated as much as 20 m into the bottom and reached as far back as Cretaceous time

The seismic evidence suggests that the sediments are remarkably uniform in thickness, averaging about 0 4 km Unfortunately, this is much too thin to agree with the figure one gets by multiplying present sedimentation-rates by the supposed age of the oceans So one very large question to be answered is What happened to the rest of the sediments ? Moreover, it seems possible that the record of early evolution, missing on land, could be preserved in the lowest sediments

There are at least four theories about the composition of the 'second layer'—all of which begin with the knowledge that it conducts seismic waves at 4 5–5 5 km /sec It may be compacted sediments, basalt, dolomite or softer sediments screened by a layer of basalt, usually it is 1 or 2 km thick

The 'third layer' has a seismic velocity of about 6 5 km /sec, it is commonly called basalt but, as Hess points out, this is more a matter of 150 years of tradition than of evidence In fact, some scientists doubt that there are as many as three layers, others think there are more

One of the interfaces (possibly the Mohorovičić discontinuity) may represent the primordial surface of the Earth It may have a surface something like the face of the Moon to-day, it may be covered by a layer of meteoritic material or perhaps a conglomerate It may give evidence of our early atmosphere and ocean, or it may have been altered beyond recognition These speculations have served to make the proposed exploratory holes even more exciting

Many of these suggestions have been discussed and debated in the literature Harry Hess believes that the Mohorovičić discontinuity represents a frozen isotherm, J F Lovering thinks it represents a temperature–pressure relationship which has caused a phase change from an eclogite mantle to a basalt crust Tuzo Wilson believes that continental andesitic material must be rising from the mantle—from greater depths than the basalts He notes that K Sapper's figure of 0 8 km ^{3}/year over geological time would account for the volume of the continents, and that a slightly higher rate of volcanism in the early stages would allow for the emission of an oceanic crust as well Sir Harold Jeffreys believes that the ocean crust is too rigid to permit sideways motion of the continents, but recently there has been renewed interest in Wegener's continental drift theory There are points of disagreement on the distribution of radioactivity, on the interpretations of seismic velocities, and on the causes of oceanic trenches

The very fact that there is not agreement is a good reason for some direct exploration (if there were no controversy there might be even greater suspicion that something was wrong)

Some of these questions will be resolved if a continuous core of the various layers beneath the sea-floor can be brought into the laboratory for study and analysis In addition, in the hole from which the core is taken measurements can be made of temperature, heat-flow, the magnetic field, plastic deformation and seismic velocity

It is therefore the objective of the AMSOC Committee to see that a continuous, oriented core to the mantle is obtained and that the hole(s) are thoroughly instrumented Some of the instruments already exist, others will have to be developed or miniaturized to fit in the hole (which will be about 6 in in diameter at the bottom) No geologist or geophysicist doubts the value of such determinations, the question is How can it be done, and for how much money ?

In *Nature* of September 13, 1958, Dr Gaskell examined some of the technical problems of deep-hole drilling However, as the AMSOC feasibility study progresses, new objectives have been developed and

Table 1 Reach of Drill required to achieve Various Objectives

	Phase	Pacific						Atlantic	
		Clipperton Island area 10° 53′ N 105° 09′ W		Guadalupe Island area 28° 45′ N 117° 31′ W		Due south of San Diego, Cal 5° 47′ N 123° 59′ W		North of Puerto Rico 20° 40′ N 66° 30′ W	
		km	ft	km	ft	km	ft	km	ft

Depth to bottom of sediment		3 3	10,400	3 6	10,900	4 8	15,700	6 0	19,600
Depth to bottom of second layer		4 2	13,800	5 2	17,000	5 5	18,000	8 0	26,200
Depth to Mohorovičić discontinuity	II	8 6	28,100	10 8	35,500	9 7	31,800	9 6	31,500

Note Geophysicists think in kilometres, but drillers work in feet
Pacific data from R W Raitt, Scripps Institution of Oceanography
Atlantic data from J Worzel, G Sutton *et al*, Lamont Geological Observatory

new drilling technology has been disclosed so that now Gaskell's views need to be revised For example, the idea of drilling from an oceanic island has been abandoned because recent studies indicate that the mantle is as deep as 17 km under the islands that have been studied Developments in floating drilling platforms make it appear that deep-water drilling is feasible in any event, besides, we need the sedimentary results A review of the temperature situation suggests that temperatures in the mantle beneath the ocean crust will be less than 200° C At several sites where seismic work has been done, the total reach of the drill stem from the surface of the water to the mantle will need to be only 30,000 ft Thus as the project develops, the objectives seem more attainable with less difficulty and expense

Table 1 shows the length of drilling pipe required to reach the surface of the various layers beneath the sea-floor at four sites which are under consideration

Inspection of these figures shows that a drill reaching to 6 km (20,000 ft) will give results on the upper three layers Beneath that it is another 3–5 km to the Mohorovičić discontinuity For this reason the project will be divided into two phases The first of these involves the modification of existing equipment for drilling holes in the upper layers The second phase—which will take us on to the Mohorovičić discontinuity—will probably require a completely new engineering design, for the total length of the drill pipe must be well over a mile beyond that used in the deepest oil well to date (25,340 ft hole by Phillips Petroleum in western Texas)

The objectives of the first phase would be to obtain the best possible samples of the upper layers while testing out deep-water drilling methods For example, no one is sure how closely a ship must be held in position in deep water while it drills, but several schemes have been proposed which would probably keep it within a circle the diameter of which is less than 3 per cent of the depth (12,000 ft or so of water) The forces due to the drag of ocean currents on the drill pipe and casing are as yet unknown because of the lack of reliable deep-current data Questions of how often casing will have to be run and how it will be supported, of how well the soft sediments can be cored and if sea water is a satisfactory drilling fluid will be answered by the first test holes

There are four floating platforms which mount intermediate-depth oil rigs drilling in shallow water off the coast of the United States Many of the problems of ocean drilling have been ingeniously solved by these operators, so that only minor modifications of standard drilling techniques are needed Several ways have been found for re-entering the hole and re-circulating drilling muds, these require that a riser pipe, conductor or casing reach to the surface It is even possible to abandon a hole temporarily and recover it again

In depths of 35–360 ft, holes have been drilled to nearly 12,000 ft *CUSS I*, for example, now drilling for oil off the California coast, is a well-designed vessel that would make an excellent deep-drilling experimental platform if it were equipped with a heavier draw-works or hoist (such as are available on the open market) and a deep mooring system

Holding a ship in position in water two and a half miles deep might be accomplished by (1) anchors which are explosion-jetted into the bottom and connected to the ship by neutrally buoyant hawse lines of synthetic material, (2) a dynamic anchoring system in which a group of outboard propulsion units (which can exert propulsive force in any direction) are centrally controlled by an operator who holds his position by watching taut-line buoys and/or listening to a vertical beam of underwater sound rising from a transducer fixed to the bottom

Thus, the mooring, drilling, setting of casing and riser pipe, coring and instrumentation all appear to be well within the bounds of our technology Engineering work has started and funds are being solicited

As the feasibility study progresses, the original cost estimates have shrunk and it now appears that the entire project might be carried out for about 15 million dollars This is not an inconsiderable sum, but it is much less than that of a rocket-propelled moon-probe, the ostensible objective of which is to learn about the nature and origin of the solar system It seems a little foolish to go off to look at the Moon when we do not know what lies a few kilometres beneath us on our own planet

The first phase of the drilling can be accomplished for about 2 5 million dollars, the second for about 9 5 million dollars It is hoped that the project will be financed jointly by private interests and by the U S National Science Foundation Certain related aspects of oceanography and of doing heavy work at sea might be supported by the U S Navy, although no direct military application is foreseen

When drilling will start is uncertain, it will depend on the length of time needed to complete preliminary work and to obtain funds Work could begin on the test holes before the end of 1959 The scientific planning of objectives, locations and instruments, the collection of necessary data and the re-survey of the most promising areas are already under way

AMSOC believes that this series of holes which will eventually sample the mantle of the Earth is likely to produce the greatest advances in man's knowledge of the Earth in our time.

ASYMMETRICAL DELIVERY IN RABBITS

By DR. LUIZ MACEDO COSTA* and DR ARPAD CSAPO

The Rockefeller Institute, New York, 21

THE experiments of Corner and Allen[1] and Allen and Reynolds[2], performed on rabbits, promised an understanding of the mechanism by which pregnancy is maintained and terminated in mammals. They also provided us with a key substance which controls these processes, the ovarian steroid progesterone.

The thirty years which followed these discoveries, however, brought disappointments. The different consequences in different species of ovariectomy or oxytocin infusion upon pregnancy, the lack of correlation between uterine activity and the concentration of progestational compounds in body fluids, and the lack of success in predicting effective progesterone therapy in women led many investigators to believe that either progestational compounds do not have a key role in the control of the pregnant uterus, or else a variety of mechanisms operate in different species.

These conclusions are challenged by a striking experiment of Nature which strongly implies that the maintenance of pregnancy is more a local than a systemic affair, thus allowing an explanation of the differences cited above. When a woman who has a duplex or bicornate uterus bears twins, one in each horn, the infants may be born several weeks apart, showing that in the same woman at the same instant conditions can be appropriate for the maintenance, as well as for the termination, of pregnancy[3].

Classical endocrinology limits our thinking to a systemic hormonal control of the uterus by which the glandular product is distributed uniformly in the target organs. This simple experiment of Nature, however, suggests to us that such a systemic control may not operate in all instances. A 'local' effect may be considered instead, when the organ of secretion and its target are in direct contact, allowing diffusion of an active compound from one cell to the next. Thus the local effect of placental progesterone has been postulated and described[4] as an alternate mechanism.

The existence of such a local mechanism could explain present controversial issues concerning the mechanism of the maintenance of pregnancy. Species differences could be looked upon not as differences in basic principles, but, for example, as differences in timing and in magnitude of the shift from ovarian (systemic) to placental (local) progesterone effect, or

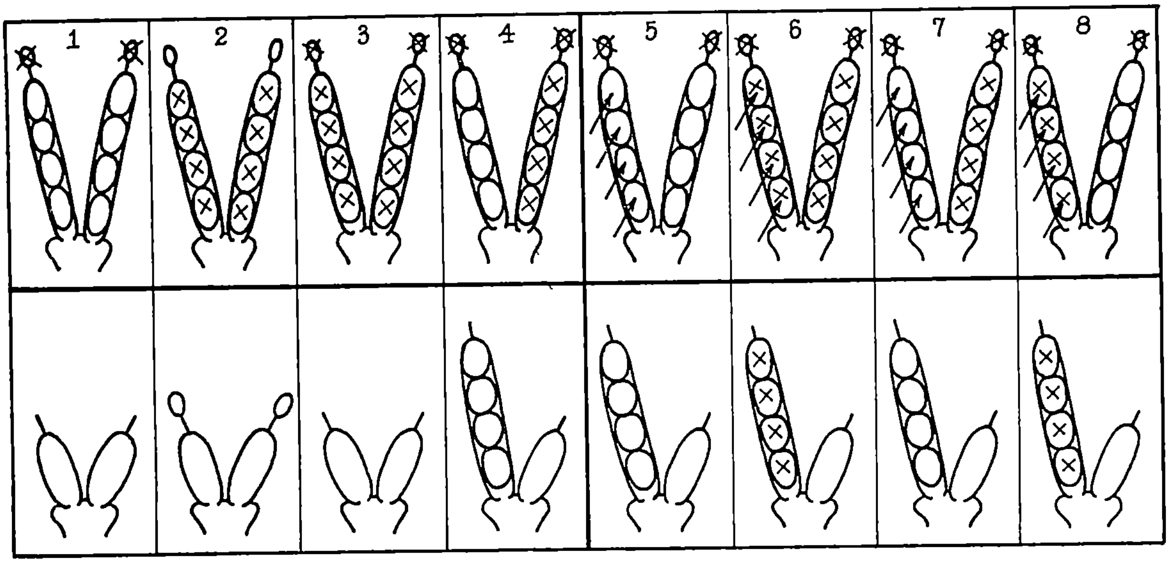

Fig 1. Schematic illustration of the type of operations used in the present study (upper row). Crosses over the ovaries represent ovariectomy, crosses over the conceptuses, placental dislocation. Arrows indicate intraamniotic injection of 2 mgm progesterone in 0.04 ml oil. The lower row represents the effect on delivery of the operation or treatment.

---

* Grantee of the Rockefeller Foundation. Present address: Department of Physiology, University of Bahia, Salvador, Brazil.

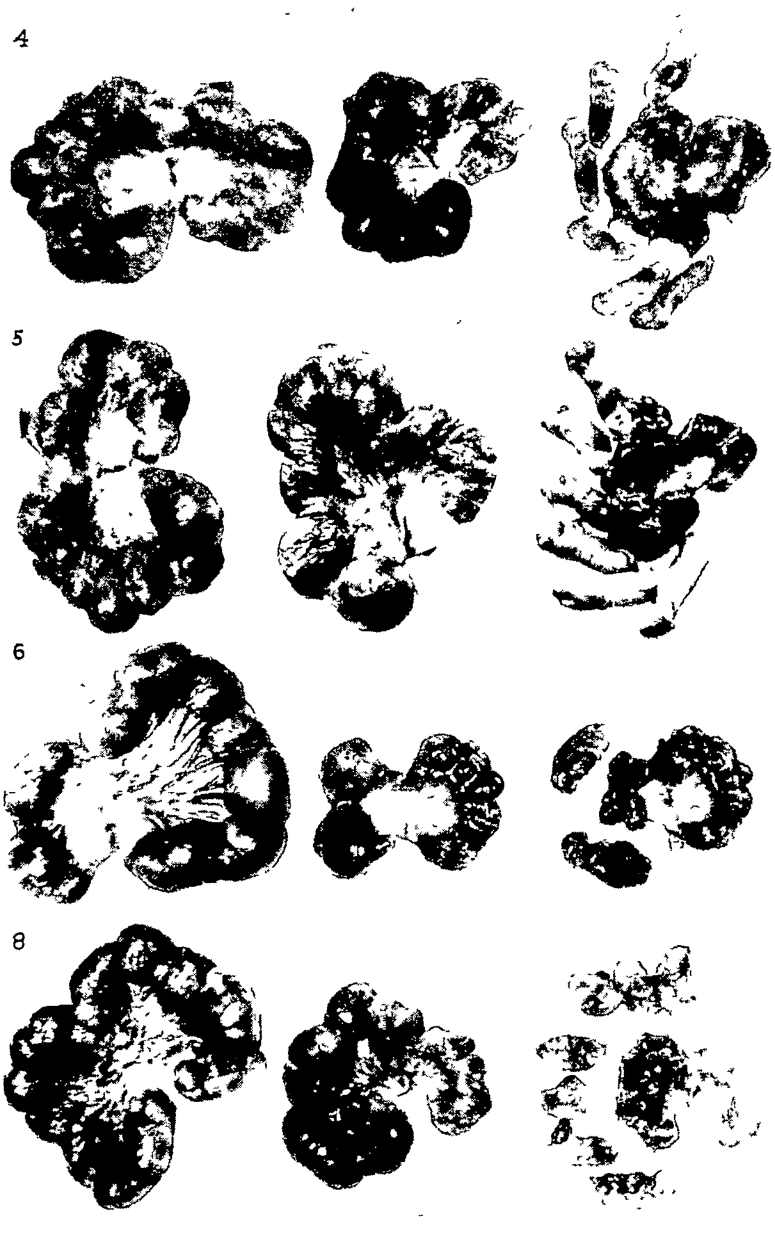

Fig. 2. Asymmetrical delivery in rabbits, induced on the twenty-fifth day of pregnancy. The numbers on the left represent the type of operation as illustrated schematically in Fig. 1. The first picture on the left is taken immediately after the operation, the second is made on repeated laparotomy after delivery is completed in one horn, and the third after the undelivered horn is opened and the fœtuses and placentas examined

as differences in the metabolism and elimination of progesterone, dependent on the exposure of progestational compounds to the systemic circulation, prior to their uptake by target organs. The concentration of progestational compounds and their changes in concentration in body fluids would not be expected to reflect quantitatively the endocrine condition of the uterus because much higher concentrations than occur in the blood or in the urine could be present in key positions at the myometrial cell; in fact, body fluids may contain only the 'leakage' of a local arrangement or what is left from destructive and eliminating processes. The lack of conclusive evidence for the effective use of progesterone in therapy would become a challenge rather than disappointment, because an effective local supply of placental progesterone could be therapeutically initiated only by a similar local application, or by forms of progesterone not subject to systemic destruction.

To demonstrate a local effect of placental progesterone on the myometrium, we studied thirty-five pregnant rabbits in the present experiments. It is generally believed that pregnancy in rabbits is entirely maintained by ovarian progesterone, not supported by placental contribution. We suspected, however, that even in rabbits there may be progesterone production, or effective metabolism, in the placenta in late pregnancy[4a,b,d]. In women, on the other hand, during the last six months of pregnancy the placenta seems to substitute completely for the endocrine function of the ovaries[5].

In our colony of New Zealand white rabbits labour can be induced with 1 i.u. 'Pitocin' (Parke-Davis), intramuscularly, in 94 per cent of the animals 31 days after mating. Only 7 per cent of the animals deliver after similar treatment (even if repeatedly applied), if the animal is less than 30 days pregnant.

We ovariectomized rabbits bilaterally (op. No. 1) on the twenty-fifth day of gestation (duration of pregnancy = 32 days) and found that 13 hr. after the operation 1 i.u. of 'Pitocin' successfully induced delivery.

If the ovaries were not removed (op. No. 2), but all the placentas in both uterine horns were dislocated (by gently pressing the uterine horn at the placental implantation site), placental function ceased and delivery was successfully induced by 'Pitocin' 20 hr. later. This is evidence that the rabbit placenta is indispensable for the maintenance of pregnancy.

If the two procedures, ovariectomy and placental dislocation, are combined (op. No. 3), labour can be induced 9 hr. later. These observations suggest that in the rabbit both the ovaries and the placentas contribute to the maintenance of pregnancy. When both these possible sources of progestational compounds are removed, the myometrium has enough stored material to defend pregnancy for 9 hr. against the labour-inducing effect of 1 i.u. 'Pitocin'. The placentas can prolong this period for four additional hours and the ovaries for 11 hr. This suggests that the ovarian contribution is three times as great as the placental.

If after any of these operations 'Pitocin' is not administered, spontaneous delivery ultimately occurs; but the time between operation and delivery, as well as the time needed for delivery, is greatly prolonged. Also, the mother may destroy or partly eat the uterine contents, which makes accurate timing and observations difficult For this reason we induced labour with 'Pitocin'

It may be argued that the rabbit placenta only stores, but does not produce, an active progestational compound The following experiment, however, suggests that the placental contribution is not only storage, but also synthesis or effective metabolism If ovariectomy is combined with the dislocation of one set of placentas, in one horn only (op No 4), this horn alone delivers 9 hr later on 'Pitocin' administration, whereas pregnancy is maintained in the other horn This asymmetrical delivery, resulting from the presence of a set of functional and another set of non-functional placentas in two horns, respectively, is indication of the production of an active compound as well as evidence of the local effect of the placenta

It might be said, however, that the active compound of the placenta is not like progesterone, but is an entirely different compound This is unlikely, since the local effect of the dislocated placentas can be substituted for by the injection of 1–2 mgm progesterone into the amniotic sac If only one horn is treated with progesterone in the ovariectomized animal, delivery is always asymmetrical The untreated horn delivers first, irrespective of whether the placentas in one horn are dislocated or not (op Nos 5–8) The time when delivery occurs reflects a functional or non-functional set of placentas, but the phenomenon is the same, that is, delivery is asymmetrical if the distribution of progesterone is asymmetrical Whether the litter is alive or not does not alter the picture, nor does the mechanical irritation of the uterine horn during the operation

These observations are best explained as follows Pregnancy in rabbits is maintained by a joint contribution of an active progestational compound by the ovaries (systemic) and placentas (local) The placental contribution is less than that of the ovaries, but both organs are needed to maintain an effective concentration of the active compound in the myometrial cell When the defence is effective, labour cannot be induced by 'Pitocin', if it becomes ineffective, labour can be induced When the systemic effect of the ovaries is suspended by ovariectomy the local effect of the placenta controls the uterus and if this local effect is asymmetrical, labour is asymmetrical

In women, an early and complete shift from ovarian to placental hormone production could result in a dominant local progesterone effect early in pregnancy This would lead to an 'endocrine asymmetry', resulting in asymmetrical function Such an asymmetry is exaggerated in a bicornate uterus when endocrine function in one placenta fails earlier than in the other Functional asymmetry of the human uterus offers attractive explanations of puzzling problems concerning normal and abnormal pregnancy and delivery

WARREN SPRING LABORATORY, STEVENAGE

IN setting up Warren Spring Laboratory at Stevenage "to carry out process research and development over a wide field not limited to particular areas of technology", the Research Council for the Department of Scientific and Industrial Research expressed its conviction that, when necessary, the Department's research stations should change in function and objective to meet the needs of changing situations The Council considered that the Fuel Research Station had largely fulfilled the aims in view when it was set up, and that current needs were satisfactorily catered for by researches going on elsewhere, it decided, therefore, to close down the Fuel Research Station, and to transfer the staff to a new Laboratory in Stevenage, with new programmes To ensure that there should be no likelihood of an impression being gained that the Fuel Research Station was being continued at Stevenage, or that the title of the new Laboratory might appear to restrict the field of activity, it is named after a lane which used to run across the site

Of the work carried out at the Fuel Research Station only two programmes have been transferred to the new Station, namely, research on the abatement of atmospheric pollution, and on the synthesis of oils and chemicals by the Fischer–Tropsch process

There had been a number of substantial indications of need for research in the field of mineral processing, and it was decided that this should form one of the new projects to be undertaken, there had also been indications of need for work on a pilot scale in various fields which the Department had not been able to meet With these pointers, it was decided to build a laboratory in a modern industrial style, to be as flexible as possible, to house in the first place a staff about the size of that of the Fuel Research Station, and with facilities for both laboratory research and pilot-scale work

The main three-story laboratory building is 372 ft long and 37 ft 6 in wide (Fig 1) It is based on a 4-ft module, which is expressed elevationally by vertical posts supporting floors and roof, and by internal posts centrally along the length The main spine corridor is set to one side of the central supports The only solid internal walls are those of the corridor and the secondary staircases, all other partitioning is of light, demountable, prefabricated construction, which can be placed in any desired position between the outer walls and the inner corridor walls, subject only to the basic 4-ft module

Gas, water, electricity, compressed air are available at every third module (12 ft) along a perimeter distribution system

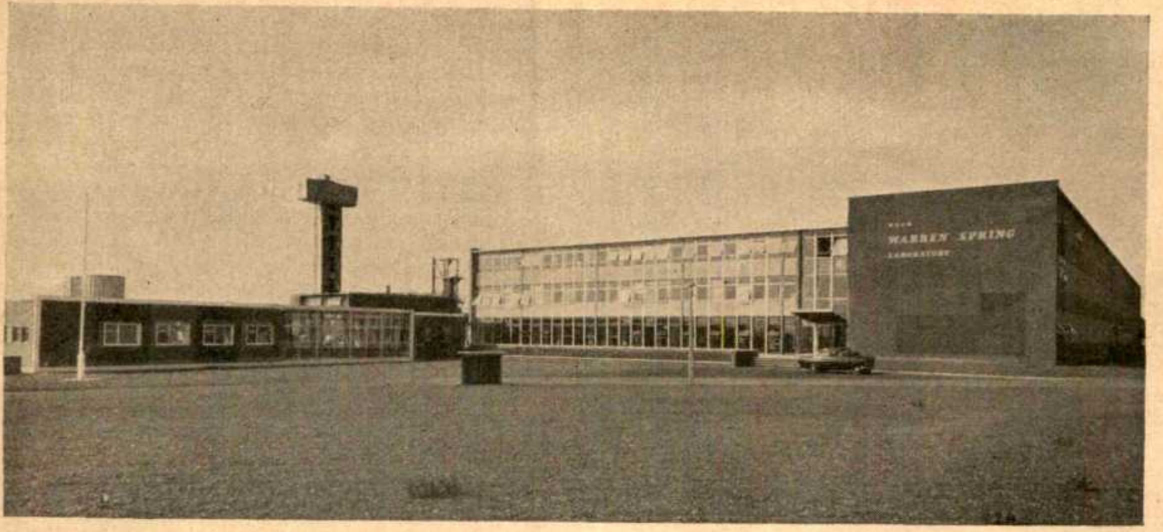

Fig. 1. The Warren Spring Laboratory, Department of Scientific and Industrial Research

The building is heated by panel-type radiators; made-up dummy panels matching them are inserted between the radiators to give the appearance of a continuous radiator panel along each wall between the concrete columns at 12-ft. centres. The radiators and the dummy panels conceal the services which run around the perimeter of the building. The dummy panels can be readily removed when service connexions are required. Fume cupboards are ranged along the inner, corridor walls, each cupboard having its own extract duct which discharges at roof-level.

The finishes are simple, self-coloured, fair-faced brickwork being used throughout, except in laboratories with special functions. With the exception of laboratories which are adapted for wet processes, floor finishes are in linoleum.

A three-story administration block runs at right angles to the main laboratory building; it is similar in construction and design except that there is a lower ceiling height.

There are three pilot-scale buildings, each 90 ft. long by 55 ft. wide by 37 ft. 6 in. maximum height. In two of them, a 20-ft. wide section is 20 ft. high only. These buildings are linked to the main laboratory block by a corridor with small-scale laboratory units on each side. The buildings have folding doors to the side bays to permit the introduction of heavy plant at any point. The structure is carried by precast concrete posts. Vertical cladding, above a brick protective walling, consists of asbestos–cement sheeting and patent glazing; the roofs are of asbestos–cement decking overlaid with bituminous felt.

The workshops and engineering stores occupy a large steel-framed building comprising six east-light bays, each 60 ft. by 30 ft. minimum headroom.

Since steam is required night and day for process purposes, two fully automatic, oil-fired, high-efficiency boilers are used, with a nominal pressure of 120 lb./sq. in.; one is rated at 10,000 lb. and one at 5,000 lb. of steam per hour. The front of the boiler house is fully glazed with a patent system permitting ready removal in sections when boiler tube replacements are necessary, so that it is possible to reduce the dimensions from front to rear. A high-level water reservoir, in reinforced concrete, has been designed integrally with the boiler flue (see Fig. 1).

Service mains run in open, splay-sided trenches to avoid the expense of underground ducts or the unsightliness of overhead gantries.

The total cost of the establishment, including buildings, services fixed, laboratory fittings, library bookshelves, and all site works was approximately £620,000.

Research Programmes

Atmospheric pollution. Purely by coincidence the closing of the Fuel Research Station occurred simultaneously with the introduction of the Clean Air Act; it was therefore particularly apposite to review the programme in starting at the new station. The work now being undertaken follows naturally from that begun at the Fuel Research Station, and is designed to meet the requirements of the Ministry of Housing and Local Government.

The principles of smoke-elimination that have proved successful in reducing smoke from hand-fired boilers on land are being applied to marine boilers. The possibility of developing after-burners to burn smoke in various situations is being investigated.

The properties of smokes from different sources are being examined with special reference to the constituents that might be injurious to health. The occurrence of oxides of nitrogen in the atmosphere under different conditions is being studied.

In the new investigations of air pollution there is a need for greater accuracy than has been possible in some of the measurements made in the past. As a matter of urgency a review is being made of the principal instruments at present in use; this work is being undertaken by the Scottish Branch of the Laboratory at Thorntonhall.

Micro-surveys are in progress to examine the concentration of various types of pollution at different types of site in a limited area. The results of such investigations will be important, for example, in helping to determine the value of smoke-control areas, and in assisting those responsible for deciding the height of siting of large industrial chimneys.

Process development. Synthesis of oils and chemicals from carbon monoxide and hydrogen is being studied as part of a project to develop, if possible, an economic process for producing oil from coal. The development of oils from coal is a two-stage process: the first stage involves the complete gasification of the coal to yield a mixture of carbon monoxide and hydrogen, and the second the catalytic conversion of the gas mixture into the desired end-products. The work at Warren Spring Laboratory is concerned only with the second of these stages. Economic considerations indicate that the most promising version of the Fischer–Tropsch process for use under British conditions is the slurry process, in which the gas mixture is passed through a suspension of powdered catalyst in molten wax at temperatures of 250–300° C., and at pressures between 5 and 30 atmospheres.

The objectives of the programme are: (1) to develop an iron catalyst of longer life and higher activity than those at present available and one that will yield a high proportion of desired end-products; (2) to select operating conditions (gas composition, temperature, pressure) to combine a high reaction velocity with a given distribution of end-products; (3) to obtain data necessary to design a full-scale reaction vessel.

Synthesis gas is produced on the site at a rate of 4,500 std. cu. ft. per hr. in a standard, water-gas generator operated by the Engineering Services Division. There are arrangements for feeding carbon dioxide with the steam so as to vary the hydrogen: carbon monoxide ratio between 1·15 and 0·6. The gas is purified from hydrogen sulphide in Gastechnik towers and washed with caustic soda to control the carbon dioxide content. It is then compressed to 15 atmospheres pressure in the first two stages of a four-stage compressor, passed through the active carbon scrubbers to remove organic sulphur compounds, and then further compressed in the third and fourth stages to a pressure of 120 atmospheres.

The study of catalysis, which has been proceeding over a number of years at the Fuel Research Station, has brought to the team concerned considerable experience which should prove of value in some of the new programmes which it is hoped to undertake in the future.

Mineral processing research and development. Dr. M. G. Fleming, of the Bessemer Laboratory of the Royal School of Mines, has been appointed consultant to this Division.

It seems probable that for some time a fair proportion of the effort of this Division will be engaged on sponsored work on particular ores; but it is hoped that basic investigations will include: (1) a study of grinding in the presence of additives such as surface-active agents; (2) the kinetics of bubble attachments to mineral surfaces, as a contribution to the knowledge in the field of froth flotation; and (3) a study of the behaviour of mineral particles in a high-tension field, and the modification of this behaviour by various surface treatments.

The laboratories are equipped to handle most laboratory-scale mineral-dressing operations such as flotation, jigging, tabling, heavy-media separation, wet and dry magnetic separation, and high-voltage separation. In the hydrometallurgical field, facilities are available for atmospheric and pressure leaching, for fluidized-bed roasting, chlorine metallurgy, and solvent extraction. Pilot-plant facilities enable primary crushing operations to be carried out on a scale up to 2½ tons per hour, and flotation plant is available for treating up to 1,000 lb. per hr. It is possible to carry out full-scale tests with radioactive tracers. The Division has a Mineralogical Section, but relies on the Physical and Chemical Services Division for its analytical work.

Many of the problems on which work is likely to be necessary concern overseas deposits. Already a number of requests for investigations have been received from overseas territories, and an Overseas Mineral Processing Advisory Committee has been set up to advise on the selection and priorities of the programmes of interest to these territories.

Chemical engineering. It will be apparent that chemical engineering must play a large part in practically all the major activities of the Laboratory, and the decision of the Research Council to transfer "the work on Chemical Engineering . . . carried out at the National Chemical Laboratory to Warren Spring Laboratory" will readily be understood.

The Division has three functions: (1) to carry out research on physical operations which play an important part both in processes which are under development in the Laboratory, and those in more general use in industry; (2) to undertake research in the field of chemical engineering sponsored by industry or by Government departments; (3) as a result of these functions to accumulate basic information in chemical engineering for use by other sections of the Laboratory and industry.

Bearing in mind work that is already going on elsewhere in the Department on heat transfer and on fluid flow, it is proposed in the first instance to concentrate on the field of mass-transfer, and in particular to obtain results which will permit more accurate prediction of the performance of gas–liquid contacting equipment, and thus to facilitate the design of distillation columns, gas-absorption towers, and reactors of the liquid-phase type, of which the Fischer–Tropsch slurry reactor is a particular example.

Four main lines of study are being followed, namely, bubble dynamics, gas-liquid mass transfer rates, fluid mixing, and specific problems in gas absorption with chemical reaction.

The National Engineering Laboratory of the Department has sponsored work at Queen Mary College, London, on the synthesis of organic compounds for use as drop-wise condensation promoters and has evaluated their effectiveness. The proposed work at the Warren Spring Laboratory is being planned in consultation with the National Engineering Laboratory and is intended as a study of the mode of action of these promoters in order to facilitate the development of compounds which will be effective for prolonged periods with a wide range of metal surfaces. It is proposed to study the mechanism of attachment of synthetic promoters to metal surfaces by methods of radiochemical labelling and to observe the subsequent history of these substances under conditions of use in heat exchangers.

Physical and Chemical Services Division. This provides a comprehensive central service in the fields of analysis, both by chemical and physical methods, instrument development, physical measurement, and photography. Special equipment includes gas chromatography, quartz and infra-red spectrometers, and equipment for X-ray diffraction and fluorescence spectrometry.

Engineering Services. This Division has a drawing office which undertakes design of pilot-scale plant for the Laboratory; it has an industrial staff of approximately 120, and well-equipped workshops.

Intelligence. In addition to the library and editorial services which are essential to any research establishment, the Intelligence Division is setting out to provide an information and project appraisal service A start has been made, for example, in building up a centre of information in mineral processing, by assembling data from a wide variety of sources in such a way that they can be used in research and industry

From what has been described it will be apparent that there is a wide choice of field before Warren Spring Laboratory, and that at the moment the main problem is that of selection, and of allocation of priorities In addition to the factors which govern the work of other laboratories of the Department of Scientific and Industrial Research, there is the task of undertaking sponsored work to a greater extent, and on a larger scale Such work may be carried out for Government departments or for industry, and it may be on a fully confidential basis The special facilities of the Laboratory will also be available for use, in certain circumstances, by teams from industry, which can work in collaboration with the research staff of the Laboratory

The programme is regularly considered by a Steering Committee, appointed by the Research Council, the present members of which are Sir Harry Jephcott (chairman), Sir Harry Melville, Dr R Holroyd, Mr D A Oliver and Mr S H Clarke.

OBITUARIES

Mr T. L. Eckersley, F.R.S.

THE death of T L Eckersley on February 15 removed another of the rapidly dwindling band of pioneers in the field of radio research, among whom he was notable both for his theoretical and practical work His interest in electromagnetic waves was aroused while he was still at school at Bedales, but it was during the First World War, after studying at University College, London, and Trinity College, Cambridge, with some years at the National Physical Laboratory in between, that he made his first big contributions to radio-wave propagation These were his explanation of 'night-effect' in direction-finding observed in Egypt and Salonika, in which he invoked the existence of an upper ionized layer giving rise to a reflected wave with variable polarization characteristics, and his observation of coastal refraction which he sought to account for in terms of the properties of Zenneck surface waves

He was thus among the first to obtain evidence of the presence of the ionosphere by the reflexion of radio waves and so began a life-long interest in the magneto-ionic theory of propagation His first work, however, on joining the Marconi Co after the War was a classical research into the properties of earth screens for increasing the radiation efficiency of long-wave aerials, followed by his analysis of the results of observations made on very long-wave transmitters by K W Tremellen and C M Allnutt during a round-the-world expedition For more than twenty years Tremellen was Eckersley's personal assistant, and his patient observational work formed the basis of the succession of papers which Eckersley wrote on short-wave radio transmission

The last of these was on scattering from 'clouds' in the ionosphere, a subject which has since become of great practical importance in the development of the ionospheric 'forward scatter' communication system Not only did all this work lay the foundation of much of our knowledge of the part played by the ionosphere in long-distance propagation, but it also led to many advances in technique, for example, in the field of accurate direction-finding and in the measurement of field-strength and polarization characteristics

Although he would not have claimed to be a pure mathematician, he had a consummate ability to apply mathematics to physical problems Indeed, many of his experimental researches were preceded or supported by elegant analysis He had a great interest in modern physics, especially in its quantum and relativistic aspects, and it was the knowledge so acquired that inspired some of his finest work in radio It was the phase integral treatment of potential barriers in atomic theory that led him to his brilliant applications to ionospheric and ground-wave propagation, while in the scattering of α-particles he found an analogy for the scattering of radio waves as a function of wave-length, cloud size and scattering angle

Eckersley had something of the absent-mindedness associated with genius, which was reflected in the style of his writing and made some of his papers difficult for others to read He was thus not as well known in the world at large as he deserved to be, but in due course full recognition among scientists came with his election to fellowship of the Royal Society in 1938 and the award of the Faraday Medal of the Institution of Electrical Engineers in 1951 He was also a well-known figure at international radio conferences, especially at the C C I R and U R S I assemblies

He was proud of the fact that he was a grandson of T H Huxley, and he was most happy in his family life, his wife being Eva, the daughter of Barry Pain, the Victorian novelist, who survives him with a son and two daughters She is an able pianist and composer, and their home at Danbury, Essex, was often visited by distinguished musical friends He was a delightful host, for he combined great courtesy with a delicate sense of humour, and though he did not play himself he had a great love of music

At the time he died he had become almost completely helpless from multiple sclerosis, the first symptoms of which had appeared more than twenty years ago In spite of increasing disability, he remained at work throughout the Second World War as scientific adviser to the Inter-Services Ionosphere Bureau at the Marconi Research Laboratories, and after his retirement in 1946 he continued to work at home for several more years

During this period he published a number of papers, his devoted wife acting as his amanuensis There is no doubt that it was her amazing courage and cheerfulness that maintained his life for so long, and indeed it was to pneumonia during the influenza epidemic that he finally succumbed The loving care which surrounded him during those last years was a source of inspiration to all who witnessed it

G MILLINGTON

Prof A O R Windaus

ON June 9 it was reported from Gottingen that Adolf Windaus had died in his eighty-third year He had retired as professor and director of the University Chemical Laboratory at Gottingen in 1938, and was made emeritus professor and director in 1944

Windaus was born in Berlin in 1876, educated at the Universities of Berlin and Freiburg-im-Bresgau and became *Privatdozent* in 1903 After a short period at Innsbruck, he was elected to Gottingen in 1915 He was awarded the Nobel Prize for Chemistry in 1928, and also received the Baeyer, Pasteur and Goethe Medals

To those interested in steroids, Windaus's name will stand with that of the late Heinrich Wieland as the greatest in the period of German pre-eminence in discovery about the chemistry and physiology of these substances Most of his publications between 1903 and 1928 were about cholesterol and described, *inter alia*, the preparation of complexes with digitonin, solanin, etc (1909, 1918), the nature of the side-chain (1913) and the relationship to coprosterol (1916) and to the bile acids (1919) Papers also appeared on stigmasterol (1906, 1924), sitosterol (1918, 1924), hydrodeoxycholic acid (1923, 1926), chenodeoxycholic acid (1924, 1925, 1926) and on 'β'-phocæcholic acid (1928) All this work and much more, including some on heart poisons and saponins, was done without modern knowledge of steroid formulæ, yet Windaus's fundamental discoveries stand largely unchallenged to-day His work on scymnol (with W Bergmann and G Konig, *Hoppe Seyl Z*, **189**, 148, 1930) was the first on the chemistry of this substance The paper with Alfred Hess, of Columbia University, New York, entitled "Sterine und antirachitisches Vitamin" and published at the session of the Gesellschaft der Wissenschaften zu Gottingen on January 28, 1927, clearly recognized that both ergosterol and an impurity separable from cholesterol acquired antirachitic activity on irradiation with ultra-violet light Parallel work had already begun in England (for example, I M Heilbron, E D Kamm and R A Morton, O Rosenheim and T A Webster, *Chem and Indust*, **45**, 932, 1926), it was energetically pursued there, and also by Windaus and his colleagues until, in 1931, success in isolating a pure vitamin D was announced almost simultaneously from Gottingen and Hampstead, London From irradiated ergosterol, F A Askew, H M Bruce, R K Callow, J St L Philpot and T A Webster (*Nature*, **128**, 758, 1931) obtained calciferol, and Windaus and O Linsert (*Liebigs Ann*, **489**, 269, 1931) vitamin D_2 · these substances were later found to be identical, although the separate names were retained

'Vitamin D_1', originally reported as pure by the German workers (*Liebigs Ann*, **489**, 252, 1931), was later proved (*ibid*, **493**, 259, 1932) to be a molecular compound of vitamin D_2 and lumisterol

For Windaus, this was by no means the end of the vitamin D problem Doubts as to the identity of calciferol (vitamin D_2) and the antirachitic vitamin of fish-liver oils persisted, and C E Bills (*Physiol Rev*, **15**, 1, 1935) summarized evidence that the antirachitic vitamin in irradiated (impure) cholesterol and in cod liver oil (as measured in 'rat units') is more potent for chicks than the vitamin (calciferol) in irradiated ergosterlly

Windaus brilliantly recalled that J Mauthner and W Suida in 1896 (*Mh Chem*, **17**, 579) had oxidized cholesterol with chromic acid to 7-ketocholesterol, and, with H Lettré and Fr Schenck (*Liebigs Ann*, **520**, 98, 1935), he reported the conversion of this substance into 7-dehydrocholesterol Irradiation of this gave a mixture from which was isolated (Windaus, Fr Schenck and F von Werder *Hoppe Seyl Z*, **241**, 100, 1936) vitamin D_3, identical with the natural vitamin obtained from tunny liver oil by H Brockmann (*Hoppe Seyl Z*, **241**, 104, 1936) at Gottingen Windaus's later papers were about the chemical nature of natural forms of vitamin D and the chemistry of irradiation products of ergosterol and 7-dehydrocholesterol

Windaus's publications, which ceased in 1944, remain as an inspiring example of what a great intellect can still accomplish in scientific discovery

G A D HASLEWOOD

Dr F Busemann

DR FELIX BUSEMANN, who died on April 30 at the untimely age of fifty-one, was an outstanding authority in his chosen subject, electrical transmission, as is his brother, Adolf Busemann, one of the leading German aerodynamicists now in America Trained at the Institute of Technology, Darmstadt, he became later assistant to the professor of electrical machine design there, and in 1934 joined the firm of Siemens Schuckert in Berlin, becoming one of a team concerned with future developments in electrical transmission This team had as one of its assignments that of high-voltage direct-current transmission Starting with a pilot scheme between Charlottenburg and Moabit, it followed by planning the Siemens Schuckert half of the major Elbe–Berlin project After the Second World War, Dr Busemann was chosen by the Darwin Panel and came to Britain in 1946 to report on the German work in this field

Busemann found the social climate in Britain so akin to his temperament that he shortly accepted an offer to join the staff of the Electrical Research Association and continue his studies on d c transmission These resulted in a masterly series of fourteen reports covering all aspects of the subject with the exception of valves, for the study of which facilities were lacking He played a major part in the planning of a pilot scheme which, had it matured, would have placed Great Britain in the van of development He was without doubt the foremost authority on high-voltage direct-current transmission in Britain, and his loss will be greatly felt

With the temporary cessation of interest in direct-current transmission, Busemann turned his versatile mind to other aspects of transmission Among these he devised, jointly with W Casson, a classic programme of full-scale experiments on power-system stability (Cliff Quay), described in a paper before the Institution of Electrical Engineers last year More recently, he had been concerned with mechanical and thermal properties of soil and utilization of power cables To all these he brought quick appreciation of decisive factors and great facility in analysis and exposition

Behind a natural modesty Busemann had great personal charm and humour as well as perception He was a musician of almost professional attainment and gave much service to his church and the social activities of the Electrical Research Association He will be remembered by all who knew him for a long time to come He leaves a widow and two daughters

L GOSLAND

Miss Grace M. Sickles

Grace M. Sickles, associate research scientist in the Division of Laboratories and Research of the New York State Department of Health, died on June 29 at Troy, New York. An eminent bacteriologist and virologist, Miss Sickles had been a member of the Health Department since 1918, with a two-year period of service (1919–20) in the Communicable Disease Laboratories of the United States Army. She was a graduate of the New York State College for Teachers and a member of the principal scientific societies in her fields of research.

Miss Sickles was associated with Dr. Augustus B. Wadsworth in an extensive series of investigations on the production and standardization of antipneumococcus, antimeningococcus and antistreptococcus sera, studying, as early as 1938, the action of immune serum in conjunction with chemotherapy in experimental streptococcus infections. Some of Miss Sickles's studies of diphtheria toxin and on the antibiotic activity of micro-organisms from the soil were carried out at the Marine Biological Laboratory, Woods Hole, Massachusetts.

Miss Sickles was the discoverer with Dr. Gilbert Dalldorf in 1947 of the coxsackie virus. The virus was identified during a study of outbreaks of poliomyelitis in New York State. It was named after the village in which the first two recognized human infections occurred. The coxsackie group now includes more than a dozen viruses which are common sources of infection in man.

Mr. W. E. Perry

The sudden death on June 5 of Mr. W. E. Perry, a senior principal scientific officer at the National Physical Laboratory, Teddington, removes one of the leading figures in the field of radioactive and radiation standardization. Born in 1903, Perry took his degree from Nottingham and joined the Laboratory in 1928. He was responsible for re-measurement of the National Radium Standards in 1934, and for the subsequent development of radioisotope measurements. Later, as head of the Radiology Section at the Laboratory, he had charge of the work on radioisotopes, X-ray dosimetry, neutron standardization and radiocarbon dating, and had an international reputation for his scientific integrity and wide knowledge in these subjects. At the time of his death, he was preparing material for the ninth International Congress on Radiology at Munich, in his capacity as chairman of Committee I of the International Commission on Radiological Units and Measurements.

NEWS and VIEWS

The British Association: New President

Sir George Thomson, master of Corpus Christi College, Cambridge, has been elected president for 1960 of the British Association for the Advancement of Science, in succession to Sir James Gray. Sir George has had a distinguished career as a physicist, as a man who gave outstanding service to the Atomic Energy Project in its early days and as master of Corpus Christi College. The son of the late Sir J. J. Thomson, he was educated at Trinity College, Cambridge, obtaining a first-class degree both in the Mathematical and in the Natural Sciences Tripos. After service in France with the Army, followed by research on aeronautical problems, he was appointed to the chair of physics at Aberdeen in 1922, where he carried out the epoch-making work on the defraction of electron beams by thin metal foils, thereby establishing beyond doubt the wave nature of the electron. For this work he was awarded the Nobel Prize for Physics in 1937. Between 1930 and 1952 he was professor of physics in the Imperial College of Science and Technology, London, and was chairman of the first British Committee on Atomic Energy, the Maud Committee, appointed in 1940. He has played a considerable part in the development of the subject ever since, being interested not less in its social as well as in its scientific aspects. Since his appointment to the mastership of Corpus Christi College, his interest in physics has continued and he has published work on gas discharges and has been chairman of Section *A* (Mathematics and Physics) of the British Association. Both on account of the great distinction of his scientific work and his interest in the wider implications of scientific advance he will be a most welcome president of the British Association.

Director of the Royal Aircraft Establishment: Prof. M. J. Lighthill, F.R.S.

Prof. M. J. Lighthill, Beyer professor of applied mathematics at the University of Manchester since 1950, has been appointed director of the Royal Aircraft Establishment, Farnborough, in succession to Sir George Gardner, who is succeeding Air Chief Marshal Sir Claude Pelly as controller of aircraft at the Ministry of Supply in October.

Prof. Lighthill has made outstanding contributions in many fields of fluid dynamics as well as in more general spheres of pure and applied mathematics. His applications of the fundamentals of mathematics to various aeronautical problems have been significant and widespread. He is particularly well known for his theoretical work on jet noise; this work, which has been largely substantiated by experiment, relates the noise to the turbulence in the jet. He has always displayed a continuing interest in the practical application of his theories, and has been for a number of years a member of the Aeronautical Research Council. Prof. Lighthill was educated at Winchester and Cambridge, and was elected to the fellowship of the Royal Society in 1953 at the early age of twenty-nine.

Royal College of Science and Technology, Glasgow: Sir David Anderson

Sir David Anderson, who is to retire from the post of director of the Royal College of Science and Technology in December 1959, was appointed principal of Derby Technical College in 1926 at the age of 31. In 1930, he became principal of the Central Technical College, Birmingham, and in a period of 16 years which spanned the arduous war years, he laid the foundations of the College of

Advanced Technology, designated as such by the Minister of Education in 1956. In this period, too, he became increasingly concerned with the problems of technical education at national level. This was especially true of his work as a member of the Percy Committee which reported in 1946, and greatly influenced the development of post-war technical education. He was president of the Association of Principals of Technical Institutions in 1932, and chairman of Council of Association of Technical Institutions in 1951. He was a member of Council of the Institution of Mechanical Engineers during 1941–42, 1948–50. First and foremost a Glasgow man, he was educated at Whitehill School, then at the then Royal Technical College, and served his apprenticeship with the North British Locomotive Company. He returned to the College as director in 1946, and the new engineering block, the recently opened students union, the Residential School of Management Studies at Bearsden, and the new students residences are visible signs of his vigorous leadership. He has continued to serve on a large number of bodies at national level, and was knighted in 1957. After the manner of present times, we may hope that Sir David will not retire from all public work, otherwise the constructive contributions of his incisive mind will be greatly missed.

Dr. S. C. Curran, F.R.S.

The Governors of the Royal College of Science and Technology, Glasgow, have announced the appointment of Dr. S. C. Curran as principal in succession to Sir David Anderson, the retiring director. Dr. Curran studied at the Universities of Glasgow and Cambridge, graduating M.A., B.Sc., Ph.D. (Glas.), and Ph.D. (Cantab.). His early researches were concerned with radiation phenomena and new methods of detection. While at St. John's College, Cambridge, and the Cavendish Laboratory, he pioneered in investigations of proton capture.

During the Second World War he shared in the successful work of the Royal Aircraft Establishment on proximity fuses and of the Telecommunications Research Establishment on the research and development of centimetre radar, having charge of one of the groups responsible for H_2S and ASV; thereafter he joined the British Mission on Atomic Weapons in the United States. At Berkeley he discovered the original form of the scintillation counter and the vacuum carbon arc. Later at the University of Glasgow he introduced the modern form of proportional counter, determining with it the form of novel beta-spectra such as that of tritium. An active research group soon grew up under his leadership.

In early 1955 he joined the Atomic Weapons Research Establishment, where he later became a chief scientist and member of the Management Board responsible for the divisions of Nuclear Research and Electronics. He also served as visiting member on the Harwell Management Board. A considerable growth of nuclear research has taken place at Aldermaston during his years there.

Dr. Curran was awarded the D.Sc. and Kelvin Prize of Glasgow in 1950 and elected to fellowship of the Royal Society in 1953.

Jean Senebier (1742–1809)

Jean Senebier, who died of "une cruelle maladie" at Geneva 150 years ago on July 22, 1809, is an anomalous figure in the history of botany. A clergyman untrained in the scientific method, yet possessing the true scientific spirit, endowed with curiosity, intelligence, and industry, he had many interests: theology, botany, microscopy, physics, chemistry, meteorology, library classification. His tiresome rhetoric prevented his being appreciated by his generation. The son of a protestant tradesman of French origin, he was born on May 6, 1742, at Geneva, where he became pastor in 1765 and chief librarian in 1773. In 1792 political unrest banished him from the city for seven years. Senebier is remembered chiefly for his studies on the influence of light on vegetation. Jan Ingenhousz, an engineer of Dutch extraction, in 1779, introduced the concept of balance of animal and vegetable life by showing that plants generate dephlogisticated air. This activity was demonstrated by Senebier between 1782–88 to be confined to the green parts of plants which, under the influence of sunlight, convert fixed air (carbon dioxide) into dephlogisticated air (oxygen). His "Mémoires physicochimiques sur l'influence de la lumière solaire pour modifier les êtres des trois règnes de la nature" in three volumes were published in 1782. The first to formulate a theory, in strictly chemical terms, of vegetable nutrition in his 'tediously prolix' (Sachs) five-volume "Physiologie végétale" (1800), he stimulated his fellow Genevan, Nicholas Théodore de Saussure, to write his "Recherches chimiques sur la végétation" (1804), which was to eclipse his own work. He was a coresponding member of the Institut de France and of the Royal Academy of Turin.

International Commission on Higher Education in Nigeria

Sir Eric Ashby (vice-chancellor of the Queen's University of Belfast and master-elect of Clare College, Cambridge) returned from Lagos on May 7, after attending the inaugural meeting of the International Commission on Higher Education in Nigeria. The Commission (*Nature*, 183, 1231; 1959), with Sir Eric Ashby as chairman, consists of two other United Kingdom members, Dr. J. Lockwood (master of Birkbeck College) and Dr. G. E. Watts (principal of Brighton Technical College), and three American members, Dr. Frank Keppel (dean of the Graduate School at Harvard University), Dr. Eric Walker (president of Pennsylvania State University) and Prof. H. W. Hannah (associate dean of agriculture, University of Illinois). The Nigerian members are Shettima Kashim (formerly Federal Minister of Social Services, chairman of Nigerian College of Technology), Prof. K. O. Dike (vice-principal and professor of history, University College, Ibadan) and Dr. S. D. Onabamiro (senior research fellow in parasitology, University College, Ibadan).

Sir Eric Ashby, speaking at the inauguration meeting in Lagos on May 4, described the decision to set up a Joint Nigerian–United States–United Kingdom Commission as a "Landmark in educational history" as this was the first time that such an international group had been appointed to study higher education in Nigeria. He assured the meeting that the Commission would be able to recommend some of the educational needs of the first twenty years of Nigerian independence could be met, and that it would do its best to prepare for Nigeria something which could be turned into action.

'Procinyl' Dyes

Imperial Chemical Industries, Ltd., has introduced 'Procinyl' dyes, a new class of disperse dyes. It is claimed that the initial four 'Procinyl' dyes display on nylon and other polyamide fibres the desirable attributes of the established disperse dyes—good levelling, good coverage of irregular-dyeing yarns, good compatibility in admixture, good temperature-range properties and good penetration They are applied in a similar manner The essential difference is that the 'Procinyl' dyes are applied initially under slightly acid instead of neutral conditions, and that dyeing is completed by an alkaline fixation stage during which certain reactive groups in the 'Procinyl' dye molecules react chemically and irreversibly with the amine or amide groups in the polyamide fibre and so produce dyeings of high wet-fastness All forms of nylon and other polyamide fibres, of both the staple fibre and continuous-filament types and including woven piece goods, knitted piece goods and hosiery, can be dyed satisfactorily with the new dyes, which may be applied, as necessary, on the jig (covered jigs for preference), on winches, in paddle dyeing machines and in circulating-liquor machines The initial four 'Procinyl' dyes—a yellow, an orange, a scarlet and a blue—permit an extensive range of shades to be produced because of the wide intercompatibility of the new dyes

Only slight or negligible reaction takes place between 'Procinyl' dyes and acetate and triacetate rayons, for which the new dyes are not expected to be of much immediate interest, although the wet-fastness achieved is generally better than with normal disperse dyes With the exception of 'Procinyl Yellow G', the dyes are of minor importance on 'Terylene' and other polyester fibres On 'Acrilan' polyacrylonitrile fibre, although 'Procinyl' dyes build up well to give heavy shades of very high wet-fastness, which results from the reaction between the dye and the basic groups in the fibre, only the yellow is of particular interest, the remaining dyes giving shades of low light fastness On acrylic fibres not modified by the incorporation of basic substances they display only limited build-up

British Ceramic Research Association

Mellor Library

The new library of the British Ceramic Research Association—the Mellor Library—was opened at Stoke-on-Trent on June 16 by Mr Frank West, vice-president of the Association and a lifelong friend of the late Dr J W Mellor, in whose honour the library has been named Dr Mellor, the well-known physical chemist, turned his mind to problems of the ceramic industry , Wedgwood, a century and a half previously, had transformed a craft into an industry , Mellor, during the first three decades of the present century, did outstanding service to that industry by giving it the basis of science that had hitherto been largely wanting As head of the Pottery Department of the North Staffordshire Technical College, Mellor taught a generation of pottery managers , as first director of research of the British Refractories Research Association (the forerunner of the British Ceramic Research Association) Mellor initiated research at a time when industrial research was a novelty But perhaps he is best known as the author of the "Comprehensive Treatise on Inorganic and Theoretical Chemistry"

Educational Research

The third issue of *Educational Research*, the journal of the National Foundation for Educational Research in England and Wales, contains articles on the teaching of mathematics, the ability to teach, the effect of environment on intelligence, school guidance services and a comparison of attainments in different types of primary school There is also a selected and annotated bibliography of works on the curriculum of the secondary school (Newnes Educational Publishing Co , Tower House, Southampton St , Strand, London, W C 2 5*s* 6*d*) In the article on the teaching of mathematics, Mr J B Biggs discusses the distaste for school mathematics so commonly reported His conclusions evaluate the relative effect of basic personality and specific likes and dislikes, particularly in the case of the maladjusted child Many so-called lazy children are seen to have found an initial block to their number learning because of their temperament This is heightened by accusations of laziness and consequent unimaginative driving by some teachers The implications of this and the other stimulating conclusions are important to the teacher who might well ask himself why there is no similar anxiety concerning English

A New Geological Documentation Service

The wealth of information available constitutes a serious problem for the future of the research in the Earth sciences Before 1939, published work could be covered by giving about one thousand references a month At present, the Service d'Information Géologique of the Bureau de Recherches Géologiques, Géophysiques et Minières indexes monthly more than 3,000 references, and it is estimated that 5,000 references should be given to ensure complete coverage of the field The situation is complicated by the number of works now appearing in little-known languages, and by the launching of new periodicals and special publications Faced with this problem, the Service d'Information Géologique of the Bureau de Recherches Géologiques, Géophysiques et Minières, which has taken over and expanded the work of the Centre d'Études et de Documentation Paléontologiques, has set itself the task of providing an extended and rapid service of basic geological information The Service d'Information Géologique scans every week about 3,500 periodicals, more than 200 of which are published in Russian The references are typed in the original language or, if they are not in Latin characters, are translated, usually into French , they are then classified in 1,200 sections under twelve main headings (mineralogy, petrography, stratigraphy, tectonics, geophysics, geological activities, geological phenomena, applied geology, general palæontology, biology, botany and zoology) The work is, of course, carried out under the supervision of scientists Each reference is indexed by title and by content The average number of indexes to each abstract card is five

Central Advisory Water Committee

On the expiry of the first period of appointment, the Minister of Housing and Local Government, Mr Henry Brooke, has reviewed the composition of the Central Advisory Water Committee and made various re-appointments and new appointments The membership of the Committee is drawn from the major interests concerned with water, for example, water supply, industry, scientists, agriculture, river boards The Minister is chairman of the Committee, and the vice-chairman is the Parliamentary Secretary, Mr J R Bevins Since its reconstitution in 1955 the Committee has published reports on the demand for water in England and Wales, on information on water resources and on the law dealing with the disposal of trade effluents

Seismological Association Meeting in Toronto

THE report of the meetings of the Section for Seismology and the Physics of the Earth's Interior, prepared by the associate secretary, Dr Markus Båth, of Sweden, has recently been published (pp 448 Strasbourg Bureau Central International de Séismologie, 1958) Most of the subdivisions into which this subject may be divided were discussed in the twenty-two sessions Detailed reports of these meetings, the presidential address by Prof K E Bullen, of the University of Sydney, the report of the meeting of the European Seismological Commission, the Committee of the International Seismological Summary and the Committee for the International Geophysical Year are included In addition, there are seismological reports from thirty-four countries, and the resolutions adopted at the assembly The whole covers some 455 quarto pages At the conference, ten sessions were devoted to seismology alone, six to joint meetings with the Association of Volcanology and two to joint meetings with the Association of Geodesy It was at an extra session at Toronto that Prof K E Bullen announced that the U S Atomic Energy Commission had released information concerning the time and place of a future underground nuclear detonation in Nevada, so that seismologists could prepare to participate in the recording The International Geophysical Year Committee discussed particularly the recording of earthquakes with epicentres in the arctic and antarctic regions , and it is noteworthy that M E Guyot is proceeding with the preparation of a seismological dictionary which it is hoped will be published without delay

Soil Survey of Great Britain

THE soil survey of Great Britain, with headquarters at Rothamsted, will occupy many years, and reports are to be published as each county is completed The magnitude of the task can be realized from the memoir on Anglesey (Agricultural Research Council Memoirs of the Soil Survey of Great Britain—England and Wales The County of Anglesey Soils and Agriculture By E Roberts Pp viii+116+11 plates London H M Stationery Office, 1958, 10*s* net), which includes also a small proportion of Caernarvonshire , nearly fifty soil series, which are the mapping units, are identified and described Anglesey is relatively flat, but there are considerable variations in the land surface due to the rugged outcrops of the Mona complex, the sharp escarpment of the Carboniferous limestones, the igneous rocks, wind-blown sands and glacial features The varying thickness of the boulder clay has contributed to the irregular undulations of most of the fields

Classification and mapping of the soils are based on the soil profile, since it reflects the action and balance of the many processes that have led to its formation , drainage has a profound effect, and is taken into account in the classification Although familiar to soil scientists and to many advisory officers, the subject is new to workers in related subjects, and to farmers The Soil Survey of Great Britain will be the foundation for a planned approach to fertilizer and cropping problems for many years, and such reports will have to be studied, and the maps referred to frequently The one inch to the mile soil map that is provided may prove too small for reference to some individual farms on or near the margins of the soil areas, but a 6-in map is available for reference at Rothamsted

Grassland Productivity

"The Measurement of Grassland Productivity" was the subject of the sixth Easter School in Agricultural Science which was held at the University of Nottingham School of Agriculture, Sutton Bonington, during April 13–16, and was organized by Prof J D Ivins Twenty papers were read, primarily concerned with techniques of grassland evaluation Assessment of productivity from the botanical point of view, in terms of animal production, the consumption of herbage by grazing livestock and grassland productivity on a farm scale were considered New varieties of herbage plants have been produced and their requirements have been explored to a great extent New techniques have been developed which have resulted in vast increases in the production from grassland, but a constant problem and hindrance to development has been—and still is—the lack of methods which may be used with validity to measure and compare grassland productivity Some 140 members from Britain and overseas exchanged experiences and ideas and discussed the limitations and applications of techniques of measuring the productivity of grassland The proceedings will be published

Safety in Mines Research

THE thirty-sixth annual report on Safety in Mines Research (pp 81+4 plates London H M Stationery Office, 1958 5*s* net) is a general review of progress in the year 1957 of the Safety in Mines Research Establishment of the Ministry of Power The report describes research undertaken in the general fields of explosives and blasting devices, explosion hazards, breathing apparatus, fire hazards, engineering and metallurgy, dust control and pneumoconiosis hazards, and in certain other fields, together with a record of testing services carried out by the Establishment A significant feature of some aspects of the work is the active co-operation and interchange of results with kindred establishments in France, Germany and Poland More than ninety topics are discussed , it is difficult to select individual topics for special mention, but perhaps attention may be directed to the work reported on the fluid mechanics of coal dust explosions, a subject of interest to all concerned with fires and explosions due to organic dusts There are, in fact, many topics reported which are of interest and importance to several industries in addition to the mining industry, including breathing apparatus, engineering and metallurgical problems of importance in conveying, winding and supports, and the study of dusts and of pneumoconiosis

Morbidity Statistics from General Practitioners

IN the series of Studies on Medical and Population Subjects, the first volume of morbidity statistics collected from general practitioners has recently appeared (General Register Office Studies on Medical and Population Subjects No 14 Morbidity Statistics from General Practice, Vol 1 (General) By Dr W P D Logan and A A Cushion Pp iv+174 London H M Stationery Office, 1958 15*s* 6*d* net) A number of practitioners agreed to keep records of all consultations with patients on their list, and the General Register Office went to considerable trouble to obtain the correct population at risk to which these consultations could be related While the practices were not chosen as a representative sample of the total population, this is the first time that a survey has been taken, and that data showing the load on general practitioners have become available on this scale The present publication shows consultation rates, and rates of patients consulting for different age and sex groups and different diseases It is expected that a further volume which will contain figures on occupational morbidity will be issued in the future

Mammals of the Belgian Congo

A PAPER by J Verschuren on the ecology and biology of the larger mammals of the Garamba National Park in the north-east of the Belgian Congo forms the ninth fascicle of the results of H de Saeger's expedition for the exploration of the park (Exploration du Parc National de la Garamba Mission H de Saeger Fascicule 9 Écologie et Biologie des Grands Mammifères (Primates, Carnivores, Ongulés) Par Jacques Verschuren Pp 225+2 planches Bruxelles Institut des Parcs Nationaux do Congo Belge, 1958) In the region studied the larger mammals are much more difficult to observe than in East Africa owing to the much denser vegetation in which they seek refuge, but the author has made good use of the two years that he was in the field and has collected much valuable information about their biology After a short introduction describing the country and the methods employed the work is arranged systematically, and each species is dealt with under the headings particulars of specimens examined, local names, geographical distribution, systematics and morphology, and ecology and biology. For most species the last section is by far the largest and is full of carefully recorded observations of the greatest interest. Fifty-one species are dealt with, distributed among the Primates, Pholidota, Carnivora, Tubulidentata, Proboscidea, Hyracoidea, Perissodactyla and Artiodactyla. The author adds that his lengthy experience of mammals in the wild has convinced him of the invalidity of many of the innumerable forms, subspecies, and races that have been so profusely described by some writers—a remark that will be heartily endorsed by other field zoologists The value of the paper is enhanced by a large number of photographic illustrations, including two plates in colour

Collision Broadening of Spectral Lines

COLLISION broadening is an important process in the formation of stellar absorption lines, and collision shifts have been discussed as a possible explanation of that part of the red shift of solar lines which is unaccounted for by the Einstein gravitational shift W R Hindmarsh (*Mon Not Roy Astron Soc*, 119, 11, 1959) has recently reported the results of the first of a series of measures of collision effects in atomic spectra The collision shift and broadening of the neutral calcium line λ 4227 A due to an external pressure of helium have been measured The line was formed in absorption by passing white light through calcium vapour in the presence of helium at various pressures less than one atmosphere The half-intensity damping width of the line was found to be 1 72 $\times$ 10^{-20} cm^{-1} per atom per cm^{3} of helium, and the shift 0 05 $\times$ 10^{-20} cm^{-1} per atom per cm^{3} towards the violet The ratio of broadening to shift on the Lindholm theory is 2 76, and the shift is predicted to be towards the red The observed ratio is much larger and the observed shift is in the opposite direction This discrepancy must be due to the involvement of the short-range repulsive forces between calcium and helium atoms as well as the long-range van der Waals forces Hindmarsh also shows that the collision shift of the calcium line is a negligible component of the solar red shift and cannot account for the difference between observed and predicted solar red shifts In the second paper following the above, W R Hindmarsh and K A Thomas show that for two argon lines the collision shifts are in reasonable agreement with the Lindholm theory

Hot Laboratory Equipment

"HOT Laboratory Equipment" is a revised and enlarged second edition of the "Hot Laboratory Catalogue", which constituted the major portion of "Chemical Processing and Equipment" (*TID*-5276), published by the U S Atomic Energy Commission as one of the several volumes for the 1955 International Conference on the Peaceful Uses of Atomic Energy The new edition (pp viii+429 Washington, D C Government Printing Office, 1958 2 50 dollars), which is fully illustrated contains descriptions of facilities, equipment and accessories for handling moderate to large amounts of radioactive materials It lists 229 items compared with 126 in the first edition, and includes newly developed items as well as items omitted for various reasons from the first edition Acknowledgment is made wherever possible to the organization responsible for the development of the particular equipment described Most of the equipment listed was developed by national laboratories or contractors to the Commission, but some were developed by private firms The contents is confined to hot laboratory equipment produced in the United States, but the reader is referred in the preface to two British publications ("Remote Handling Equipment", by A Apperly, Atomic Energy Research Establishment, *E/R* 1291, and "Radioisotope Instrumentation and Accessories", by D Taylor and A G Peacock, Scientific Instrument Manufacturers' Association, 1955) for information on similar equipment available in Great Britain

Textiles and Dyes at the University of Leeds

THE eighty-fourth report of the Textile Industries and Dyeing Advisory Committee on the work of the Departments of Textile Industries and Colour Chemistry and Dyeing in the University of Leeds (pp 47 Leeds The University, 1959) covers the session 1957–58, in which applications for admission greatly exceeded places and very full programmes of teaching and research were maintained In the Textile Industries Department, full-time students numbered 351 and in that of Colour Chemistry and Dyeing 50 Lists of publications are included In textile physics work continued in X-ray diffraction electron microscopy, infra-red absorption, and sedimentation in the ultracentrifuge A second electron microscope was installed In textile chemistry a method of producing a permanent lustre on all-wool fabrics has been developed and the chemical mechanism of permanent set especially that obtained with sulphite–bisulphite solutions, was re-examined Work on the effect of variations in the nature of the keratin in the assessment of wool quality continued The constitution of some suint pigments which may be involved in the staining of wool, the surface activity of steroids and pyrolytic degradation of cholesterol are being studied, and a brief examination of the dielectric properties of lanosterol indicated its suitability for use in impregnated paper capacitors

In textile engineering good progress is reported in the analytical study of loom noise and in a study of the drying of textiles In textile technology, work on the chemistry and practice of finishing fabrics made from both wool and man-made fibres continued and on the measurement of yarn irregularity The chemical properties of pigmented wool, the action of concentrated sulphuric acid on wool, the removal of compounds of high molecular weight from textile materials and the degradation and yellowing of nylon were also studied

In the Department of Colour Chemistry and Dyeing the course of the changes which occur in the reaction of aromatic carbonyl compounds with basic substances was examined, a study of stilbenequinone and its derivatives was completed, and work on elimination of groups from vat dyes on reduction and on the reactions of sulphinic acids with azo compounds and azines continued A group of diazonium salts soluble in benzene was prepared, and a study of the interaction of aminoanthroquinones and aminofluorenanes with nitrobenzene and α-nitronaphthalene was completed, as well as work on the vapour pressure and absorption energies of some anthroquinone and azo dyes The influence of the acetyl value of acetate rayon on the rate of dyeing and affinity for disperse dyes is being studied

Journal of Nutrition

Dr Richard H Barnes, dean of the Cornell University Graduate School of Nutrition, Ithaca, New York, has been appointed editor of the *Journal of Nutrition* He succeeds Dr George R Cowgill of the Yale Nutrition Laboratory, who has served as editor for twenty years Dr Cyril L Comar, director of the Laboratory of Radiation Biology, New York State Veterinary College, has been appointed associate editor The appointments became effective July 1, 1959 The editorial offices of the *Journal of Nutrition* are being moved from Yale University to the Cornell University campus Manuscripts should be sent to Dr Barnes at the Graduate School of Nutrition, Savage Hall, Cornell University, Ithaca, New York

Nature Conservancy Awards for 1959

The Nature Conservancy announces the following awards of research studentships for postgraduate training in ecology, tenable for periods up to three years at the universities shown *Botany* J K Marshall (Cambridge), D P Nicholas (Liverpool), W J Roff (Cambridge), J T R Sharrock (Southampton), D T Streeter (London), *Zoology* M L Clark (Leeds), E R Creed (Oxford), J M Edington (Durham), C J Henty (Oxford), J B Nelson (Oxford), G C Phillips (Oxford), *Geography* I G Simmons (London)

University News

Edinburgh

Prof A D Ritchie, professor of logic and metaphysics in the University of Edinburgh, retires on September 30, his long and distinguished career was mentioned in reviewing his recent book, "Studies in the History and Methods of the Sciences" (*Nature*, July 4, p 4) Prof E E Harris, formerly professor of philosophy in the University of the Witwatersrand, has been appointed acting head of Prof Ritchie's Department for one year

Swansea

The following appointments have been made in the University College of Swansea for the session 1959–60, Dr J R Cross, superintendent of the Chemistry Laboratories, Miss Glenys Thomas, map curator and cartographer in the Department of Geography, Mr P W Davies, assistant lecturer in metallurgy, Dr H E Evans, lecturer in engineering, Mr B W Preece, assistant lecturer in engineering

Announcements

Mr Walter Garner, formerly chairman of the Yorkshire Section and at present chairman of the London and District Section of the Textile Institute, and Dr A R Urquhart, honorary secretary of the Institute and an assistant director of the British Cotton Industry Research Association, have been awarded the Service Medal of the Textile Institute

Prof H Mark, director of the Polymer Research Institute of the Polytechnic Institute of Brooklyn, New York, will deliver the Fourth Baekeland Memorial Lecture under the title "Recent Progress in Polymer Chemistry" The Lecture will be delivered on October 22 at the Royal Institution, Albemarle Street, London, W 1

The International Commission on Zoological Nomenclature has been given accommodation in the British Museum (Natural History) This will greatly facilitate the work of the Commission by reason of the unique library facilities and wide range of specialist advice available Correspondence should in future be addressed to Mr N D Riley (Honorary Secretary), International Commission on Zoological Nomenclature, c/o British Museum (Natural History), London, S W 7

The second session (1959–60) of the Welsh Soils Discussion Group will open with a meeting in the Department of Agricultural Chemistry, University College, Bangor, on October 28 The subject for discussion will be "Mineralogical Aspects of Soil Science", the introductory speakers will be Dr F Smithson and Mr R I Davies (Bangor) and Mr. D F Ball (Nature Conservancy, Bangor) Further information can be obtained from Mr J A. Taylor, Geography Department, University College, Aberystwyth

The Scottish Conference on "Relationships in Industry Some Changing Concepts of Management", which is being organized jointly by the British Institute of Management and the Ministry of Labour, will be held at Gleneagles Hotel during October 23–24 It will be opened by Sir Alexander Fleck, chairman of Imperial Chemical Industries, Ltd Further information can be obtained from the British Institute of Management, Management House, 80 Fetter Lane, London, E C 4

In November 1859 Charles Darwin published "The Origin of Species" and Queen Victoria granted the Royal Title to the Royal Society of Victoria To mark these two centenaries, the Society is organizing a symposium on the Evolution of Living Species, to be held in Melbourne during December 7–11. Dr Ernest Mayr of the United States will be the guest speaker Further information can be obtained from the Honorary Secretary, Royal Society of Victoria, 9 Victoria Street, Melbourne, C 1, Victoria

Referring to the review in *Nature* of June 27, p 1766, Messrs Chapman and Hall state that the present American price of Cox's "Planning of Experiments" is 7 50 dollars

MOLECULAR AND ATOMIC MOTIONS BY RADIO-FREQUENCY METHODS

MAXWELL-AMP.E.R.E. CONFERENCE

A JOINT meeting of the Colloque AMPERE (Atoms et Molecules par Etudes Radio-Electriques) and the British Radio Frequency Spectroscopy Group was held during April 1–3 at Queen Mary College, University of London The meeting was attended by more than two hundred scientists, mostly from the British Isles but with strong representation from France, Holland, Switzerland and the Eastern European countries in particular The subject for discussion at the Conference was, "Molecular and atomic motions in liquids and solids by radio frequency methods" In the tradition of the AMPERE meetings the subjects covered were, dielectrics, nuclear magnetic resonance, quadrupole magnetic resonance and electron spin resonance. However, the range of the papers was constrained somewhat more than has been usual at the AMPERE conferences by the specification of a subject for discussion, albeit rather widely interpreted

The forty-four papers presented showed the power and range of the radio-frequency methods in studying molecular and atomic motion and there was an impressive consistency and similarity in the information produced by the very different experimental methods It was regrettable that time did not allow the inclusion of mechanical and ultrasonic absorption measurements although these received mention in several of the papers

Since many people versed in one discipline attended lectures in another, the occasion was a suitable one for having a general introductory lecture in each subject, and these were given by Prof. H Frohlich (Liverpool) on "Dielectric Theory", Dr J G Powles (London) on "Motional Effects in Nuclear Magnetic Resonance" and by Dr M Buyle-Bodin (Grenoble) on "Motional Effects in Pure Quadrupole Resonance" Even so, many of the discussions became extremely technical and specialized and the difficulty in having a meeting on a subject which cuts across the traditional interests and compartments of science was apparent This difficulty is a common one in conferences these days although highly specialized discussion is said to be evidence of 'maturity' of a subject It is regrettable that the cross-fertilization which should be brought about by conferences such as this one is so difficult to achieve It is therefore very valuable to have organizations 'd'informations mutuelles' such as the Colloque AMPERE and the British Radio Frequency Spectroscopy Group, the membership of which cuts across the traditional disciplines and contrasts with the extreme specialization of many organizations

It was a source of great sorrow to all present, and particularly to the writer, that Prof Freymann (Paris), the inspiration of the Groupement AMPERE, was unable to be present owing to illness, and that this should be the first AMPERE Conference he has missed

The conference overcame in large measure the difficulties occasioned by the fact that it was held outside France for the first time (apart from a foray to Geneva in 1957) and was well attended by French scientists Although some 50 per cent of the papers were presented in French, the British members appeared to survive the ordeal without severe discomfort, and it may be that the teaching of French in our grammar schools is not as ineffective as is commonly supposed. The language difficulty was lessened by the provision of pre-prints of most of the papers

It would obviously be impracticable to mention all of forty-four papers and a brief summary only will be presented in an attempt to give some idea of the scope of the conference

The conference was opened by Prof H Frohlich, who gave a masterly summary of the present situation in the theory of dielectrics, the main point of which was that the whole of the general theory has been worked out The continuing appearance of papers on 'general theory' are no more than mathematical exercises, and whether these results are correct or not they are irrelevant This point of view was undoubtedly novel to many present He elaborated his position by discussing the whole field of dielectric loss in which he distinguished four types all but one of which are well understood He was particularly concerned with the extent to which the theory can be dealt with macroscopically, which is of first importance because of the long-range nature of dipolar forces, and with the number of independent parameters required for an *understanding* of the phenomena involved He did point out nevertheless that a great deal of work remains to be done in the theory of dielectrics but that this should be concerned with the detailed interpretation, using models and so forth, and in the search for information about materials and processes

This lecture led on naturally to the more detailed discussion of a number of papers on dielectric loss in liquids and solutions, which depends in large measure on molecular properties and in which the 'model' aspect was very evident.

J D Hoffman (National Bureau of Standards, Washington) introduced a session on solids with an account of his work on systems having multiple relaxation times leading to bimodal, or even multimodal, loss curves which he explains in terms of multiple minima in the energy as a function of the orientation of a dipole A paper by H Granicher and C Jaccard (Zurich) summarized the present position in the interpretation of the dielectric properties of ice B Szigeti (Liverpool) described his recent work on a so far unobserved librational absorption process which should be found in crystalline long-chain substances

There were a number of papers on the dielectric properties of systems in which water or a gas was adsorbed on materials such as silica gel

The session on nuclear magnetic resonance was opened by J G Powles (London), who gave a summary of motional effects which can be studied by nuclear magnetic resonance, including numerous examples of the various types of effect which may occur He pointed out that examples of many of these would be found in the following papers but gave a number of extra ones in order to provide a balanced picture of the potentialities of the method

There were several papers on motional effects in hydrocarbons which were concerned with the elucidation of the molecular motions occurring in these molecular crystals. E. R. Andrew (Bangor) summarized his recent work on macroscopic motional effects, extending his considerations to quadrupolar effects and showing in particular how macroscopic motional experiments may help in deciding the nature of a magnetic interaction. A paper by K. Luszczynski (London) discussed the rather complex motional effects in the polymer poly*iso*butylene. J. A. E. Kail and J. G. Powles (London) had studied the molecular motion in *iso*butyl bromide, which is of interest since it is readily obtained either as a crystal or as a supercooled liquid over a wide temperature-range. The value of nuclear magnetic resonance measurements made at kilocycle frequencies was pointed out by G. Hochstrasser (Geneva). The interest in comparing nuclear resonance and self-diffusion parameters in mobile liquids of long-chain compounds was discussed by D. Cutler and J. G. Powles (London). M. P. McDonald (Heston) presented high-resolution results on amphiphilic solutions which have liquid crystal phases. D. J. Kroon and C. v. d. Stolpe (Eindhoven) reported nuclear resonance measurements which throw light on the movement of hydrogen in the alloy Th_2Al, which is used as a getter. H. Winkler (Leipzig) discussed the nuclear resonance of water sorbed on alumina, which links up nicely with the corresponding measurements reported in the Dielectrics Session by G. Ebert (Leipzig). I. Solomon (Saclay) reported a new method of measuring long nuclear resonance relaxation times.

The session on pure quadrupole resonance was opened by M. Buyle-Bodin (Grenoble), who gave an excellent summary of the motional effects which are to be found and included an appreciation of his own valuable contributions in this field. J. L. Ragle (Amherst, Mass.) reported work which indicated the motional effects in 1,2-dichloroethane. It was reported by F. Herlach, H. Granicher and D. Itschner (Zurich) that a new phase transition had been found in potassium iodate by nuclear quadrupole resonance, and the value of this method in detecting such 'weak' transitions was pointed out.

Time was then given to an informal discussion on commercial instrumentation in magnetic resonance. A number of firms briefly described their products and this was followed by a general discussion. The time and occasion were appropriate since the amount of commercial instrumentation available is at present rapidly increasing. It was of interest to note the great difference in tone and objectivity between a commercial and a scientific discussion.

In the session on electron spin resonance it was evident that motional effects are less important and appear very much as a by-product. D. J. E. Ingram, M. Fujimoto and M. C. Saxena (Southampton) reported experiments indicating two types of motion: one in which rate of radical diffusion in an organic glass could be measured, and another in which the spectrum differed with temperature, which was taken to indicate an effect due to reorientation of methyl groups within the radical. It was unfortunate that no paper was offered in which the motional averaging of the anisotropic hyperfine splitting was discussed. In a striking paper, K. H. Hausser (Heidelberg) showed how the resolution of hyperfine spectra in free-radical solutions depends on the optimum condition for observation of detail in the spectrum, which is essentially a motional effect and which must be arranged to give optimum relaxation parameters. Presumably motional effects can be studied in this way although this was not emphasized in the paper. A. Landesman (Saclay) reported a study of the $(SO_3)_2NO^{2-}$ ion in solution by measurement of the solvent protons.

During a session on motional effects in irradiated materials, J. S. van Wieringen and A. Kats (Eindhoven) reported paramagnetic resonance spectra of irradiated fused silica at liquid-nitrogen temperature which were due to hydrogen atoms formed from water impurities. The variation of these signals with temperature and time was used to study the motion of the hydrogen atoms. A. Losche (Leipzig) reported proton magnetic resonance measurements on nylon-6 which had been subjected to doses of comparatively weak γ-radiation over periods of several months. The radiation causes chemical changes which affect the molecular mobility of the polymer and hence the nuclear signals. It was suggested that this might be a suitable method of measuring integrated radiation doses when the intensity is rather low.

The papers presented at the conference, but not the discussions, are being published in a special issue of *Archives des Sciences* (price 25 Swiss francs). Copies may be obtained by writing to the Secretariat AMPERE, Institut de Physique, Bd. d'Yvoy, Geneva, Switzerland.

The next Colloque AMPERE will be held in Pisa, Italy, in September 1960. J. G. Powles

SEMICONDUCTING SILICON CARBIDE

One of the most important aspects of semiconductor physics in recent years has been the search for materials which yield devices capable of operating at higher temperatures than germanium and silicon. In this search, silicon carbide has been regarded as an important candidate, although, indeed, there are others. For silicon carbide, the high temperature of formation implies a high degree of stability at all temperatures likely to be encountered by devices. Moreover, the material can be regarded simply as silicon in which half the atoms have been replaced by the chemically similar carbon. In this way, much of the available information concerning, for example, the effect of impurities in germanium and silicon should be applicable to silicon carbide also, considering that the bonds are almost wholly covalent. Again, the relatively wide band gap would promise a large measure of electrical stability over a wide range of temperature. These advantageous features tend, unfortunately, to be balanced by a major practical difficulty, namely, that of growing single crystals with a controlled content of additives and crystal defects.

In order to explore these problems and to make a general assessment of our present knowledge, a major conference was recently held at Boston during

April 2–3, sponsored by the U.S. Air Force Cambridge Research Center and under the chairmanship of Dr. J. R. O'Connor. The U.S. Air Force Cambridge Research Center has for some time been the principal agency engaged on the task of initiating, supporting and co-ordinating a comprehensive research programme on silicon carbide, covering fundamentals and devices on a long-term basis. Forty-six papers were presented, dealing with such matters as the phase relations of the silicon – carbon system, methods of crystal preparation (by sublimation, gaseous cracking, epitaxial growth and from solution), silicon carbide as a solid (crystal structure, surface morphology, oxidation), silicon carbide as a semiconductor (band structure, electrical and optical properties) and silicon carbide devices.

Recent phase studies show that silicon carbide does not decompose thermally below 2,830° C., contrary to earlier reports. Large single crystals of the material have, of course, been available for a long time; but, as a rule, these appear only accidentally in the course of manufacture of silicon carbide in large furnaces which do not permit accurate control. In comparison, the laboratory methods listed above lead to crystals of much higher purity (for example, as assessed by neutron activation and spectrographic methods) but of very much smaller size. It has been widely suggested that the scale of the operation may have an important influence on the outcome and that, in any event, the temperature gradient in the direction of growth should be brought under control. Crystal growth from solutions of silicon or iron – silicon alloys supersaturated with carbon has yielded plates up to 8 mm. across and 0.5 mm. thick. The optimum growth conditions have not yet been determined. The structural studies are, of course, devoted to the well-known property of silicon carbide of forming a great variety of polytypes which are not yet fully understood. There is as yet no evidence of any definite connexion between polytype formation and impurity content, but interesting relationships are known to exist between the polytypic structure and the geometry of the spiral growth surfaces.

The width of the forbidden energy gap, derived from optical absorption measurements, has been found to be 2.86 eV. at 300° K., with a temperature coefficient of -3.3×10^{-4} eV./deg. C. The existence of impurity bands has been inferred from observations of electroluminescent spectra as a function of temperature and current density. The electroluminescence itself is now firmly believed to be due to the injection of minority carriers through *p–n* junctions and their subsequent recombination in luminescent centres, even though many details still remain to be clarified. An electron mobility of 32 cm.^{2}/volt-sec. has been quoted for material containing 10^{15} to 10^{17} donors/cm.^{3}

The question of departures from stoichiometry is still highly controversial. It is not yet known whether such departures exist to any significant extent and whether they lead to donor or acceptor formation if they do. The minority carrier lifetime, measured by observing the photoconductive decay following the cessation of an optical stimulus, is very short but can reach a few tenths of a microsecond. This fact, coupled with the relatively small carrier mobility, makes the design of silicon carbide transistors a problematical prospect. It is, however, believed that such transistors, whether unipolar or bipolar, could now be made if the best available crystals were used in conjunction with the most sophisticated micromanipulation techniques. In practice, gallium phosphide, with its lower melting-point (~ 1,340° C.), wide band gap (2.25 eV.) and higher carrier mobilities may prove to be an important competitor. Apart from this, there are fair prospects for device applications in the field of high-temperature rectification. *p–n* junctions can be prepared by the usual doping techniques and a finished encapsulated rectifier capable of operation at 500° C. was described. The more familiar application of silicon carbide for the manufacture of non-linear current devices ('varistors') is still of great interest. The behaviour of these devices is now reasonably well understood, even though the detailed circumstances may be complicated by thermal effects, impact ionization and the current-dependent charges in intergranular surface states.

The proceedings of the conference were summarized by a review panel under the chairmanship of Dr. W. Shockley. They will be published in book form by Pergamon Press.

H. K. HENISCH

AVAILABILITY OF PLANT NUTRIENTS

A MEETING of the British Society of Soil Science held, by kind permission, at the London School of Economics on April 9, was devoted to consideration of the factors which determine the availability of nutrients in the soil. Five papers were presented and discussed.

Dr. R. K. Schofield (University of Oxford) referred to the successive stages in transfer of nutrients from the soil surfaces, through solution to the roots where metabolic assimilation takes over; any one stage may provide a limiting factor in the supply to the plant and the problem is to unravel their relative importance. Extraction with a weak electrolyte such as calcium chloride goes some way towards characterizing the intensity factor of phosphorus in the soil, but use of phosphorus-32 and calcium-45 has given a better understanding of the labile pool of these nutrients and a measure of the capacity factor. The low concentration of phosphorus extracted by calcium chloride compared with the amount isotopically exchangeable suggests that the time of transit between absorption sites is small. Uptake by roots introduces another factor, but pot experiments with cabbages, barley and lupins using phosphorus-32 showed no differences in the supplies accessible to these plants. Judged by the specific activity of the phosphorus in the plants and in various soil extracts, calcium chloride solution or water gave a better assessment of availability than did many of the solutions often used in soil analysis; these liberated phosphorus which was not available to plants.

Dr. P. Newbould (University of Oxford) described experiments with calcium-45 uniformly mixed with two soils in pots. The specific activity of calcium absorbed by barley and ryegrass fell steadily during growth owing to a slow equilibration with forms of calcium other than exchangeable calcium. As roots locally depleted supplies of labile calcium, more calcium came into circulation. Exchangeable and available calcium can no longer be regarded as synonymous, and the latter is affected by the activities of plant roots.

Dr. R. Scott Russell (Agricultural Research Council Radiobiological Laboratory) directed attention to different steps in nutrient absorption by roots and stressed that the effective area of absorption was restricted to a region near the apices. The availability of a nutrient to a plant may be influenced by interactions with other ions either by competition or by physiological changes. Dr. Scott Russell referred to work which suggested that the individual root-absorption characteristics of different crops influenced the apparent availability of a nutrient such as phosphorus in a soil.

The probable parts played by micro-organisms were described by Mr. J. S. Waid (Levington Research Station, Ipswich), who stressed that much of the evidence was circumstantial and required further substantiation. Organisms are known to be able to increase the water solubility of nutrients by oxidation or reduction, and by the decomposition of organic materials; the availability of nitrogen is intimately bound up with biological processes. Soil organisms may compete with roots for soluble nutrients especially when stimulated by supplies of organic materials, some of which may be provided by the roots themselves; production of carbon dioxide or toxins may affect the physiological activity of plant roots.

Dr. G. W. Cooke's paper (Rothamsted Experimental Station) described the problems of assessing the nutrient status of a soil for advisory purposes; here the criterion is the probable economic response of various crops to fertilizer dressings, and in this field soil analysis has not made much progress. The results generally distinguish between the broad levels of nutrient status for phosphorus and potassium, but in order to avoid crop failure in the exceptional cases the overall application of these fertilizers is about double the amount that is economically justified. The assessment of the nitrogen status of soils is even more uncertain, and there is an acute need for the development of fresh analytical techniques tested against field trials. Dr. Cooke suggested that a more successful approach might lie in the use of soil analysis for 'fertility control' whereby a record was maintained of the fertility status of a soil so that warning was given of abnormalities before they became acute.

In the open discussion which followed these papers the following points were among those made:

Correlation between soil analyses and field responses is poorer in tropical and other under-developed areas than it is in Britain, yet the need for reliable soil tests is even greater. Different speakers stressed the importance of studying the anomalous soils in order to discover which factors affecting the availability of nutrients have been neglected. Analysis should not be divorced from examination of profiles since often these showed some physical property which meant that, while nutrients might be available in the chemical sense, they were inaccessible to plant roots.

The value of plant analysis in relation to fruit crops and forestry was mentioned; by this means it may be easier to recognize an interaction effect which is not revealed by soil analysis. Some progress was also reported on the development of techniques for determining the nitrogen status of soils; this seems to be greatly affected by re-wetting of air-dry samples.

D. V. CRAWFORD

AHMEDABAD MILLOWNERS' TEXTILE INDUSTRY'S RESEARCH ASSOCIATION

A TEXTILE research laboratory, created and sustained by the co-operative effort of the industry and the Government of India, was envisaged by the Ahmedabad Millowners' Association as early as 1944. In 1947, the Ahmedabad Textile Industry's Research Association was registered with a membership of seventy-one mills. Ahmedabad thus became the proud pioneer in establishing a co-operative research centre for the cotton textile industry in India.

The Association started functioning in 1949, and its impact was soon felt by the industry in and around Ahmedabad. It became clear to the original members that the benefits accruing from research could with advantage be placed at the disposal of the industry on a nation-wide basis. With this object in view, the constitution of the Association was suitably amended so that mills outside Ahmedabad could become members and enjoy the same research benefits as the original founders. The present strength of members including all categories stands at eighty-eight mills and allied concerns, comprising thirty lakhs of spindles and sixty-three thousand looms—roughly one-third of the Indian cotton textile industry.

The policies of the Association are decided by an autonomous body known as the Council of Administration. At present, the twenty-member Council is made up of representatives of management, nominees of the Government of India, the director and secretary of the Association as well as directors of other research organizations, and co-opted scientists. The Textile Commissioner is one of the nominees of the Government of India. Shri Kasturbhai Lalbhai has been the chairman of the Council from its inception.

The composition of the Council ensures a balanced and co-ordinated research policy which takes into account similar efforts by other textile research institutions and national laboratories. Further links with Government and with national research in related spheres have been established through the Ministry of Scientific Research and Cultural Affairs.

The Association began modestly in 1949 in three rooms in the Mafatlal Gazalbhai Science Institute. The foundation stone of the present building, which is housed on a 50-acre campus to the west of Gujarat University, was laid by Sardar Vallabhbhai Patel in November 1950. The building was completed towards the end of 1953 and formally declared open by Shri Jawaharlal Nehru in April 1954.

The laboratories of the Association are equipped with instruments for research in textiles and allied fields. Some of these instruments have been designed and fabricated there The physics laboratory has equipment for studying the structure and physical and mechanical properties of fibres, yarns and fabrics The chemistry laboratory has, in addition to the usual facilities for analysis of textile materials, a unit processing section equipped for the treatment of samples of yarns and fabrics through processes such as bleaching, dyeing, printing and finishing The pilot mill is a versatile unit and its machinery offers a wide range of processing sequences in spinning, weaving and chemical processing The workshops are equipped for the dual purpose of servicing mill machinery and of designing, fabricating and servicing laboratory instruments.

The Association owes its success in large measure to the enthusiasm of its workers Most of these workers have been recruited from universities and initiated into specialized fields of industrial research When necessary, training has been supplemented by periods of study in overseas institutions Technical assistance schemes such as the Point Four Programme, the Colombo Plan and the Imperial Chemical Industries Fellowships have been of great value. From a small group of about twenty-five workers in 1949, the Association has developed into an organization with a total strength of 200, which is made up of 75 scientists and technologists, 25 administrative workers, 40 skilled operatives and 60 service personnel

The services of a number of foreign specialists have been secured from time to time with the assistance of organizations like Unesco and the International Labour Organization, in 1956 the Association was recognized by Gujarat University as a teaching centre for postgraduate research At present most of the research students are awarded scholarships or fellowships by the Government of India, the Council of Scientific and Industrial Research, Gujarat University and the Association

In a technologically under-developed country, it is often the path of least resistance to apply to one's own use the findings of more advanced countries During the early days, the Association emphasized the application of scientific and technical knowledge already available to the problems of the industry This practice of helping the industry to implement the findings of research has paid rich dividends and constitutes one of the main activities of the Association at present In the process, industry has become wide awake to the potentialities of original research and has cordially welcomed the Association's efforts

While being primarily a research organization the Association tries to help industry in other ways Training in various skills, such as management and supervision, statistical methodology and testing procedures, is given to the staffs of member mills Such trained personnel not only become better equipped for their work, but also help in securing more effective implementation of the Association's programmes Often, they form the nucleus of research and training groups in their own organizations

GLASSHOUSE CROPS RESEARCH INSTITUTE

THE annual report of the Glasshouse Crops Research Institute for 1957* shows that, although full facilities are not yet available, the physical development of the Institute has made good progress and some of the major problems associated with commercial glasshouse practice have been investigated Physiological studies of the growth of tomatoes have continued, and practical problems of plant spacing and pruning have received attention Previous studies at Cheshunt and the Institute have shown that retention of lateral branches below the first truss, on widely spaced plants, of the variety 'Potentate' gave a yield nearly three times as great as on single-stemmed plants It was of importance to discover whether this constituted an increase in yield per unit area of glasshouse space, the factor of most concern to the grower This has been investigated in preliminary experiments by comparing the yields from plants having no side shoots and plants in which side shoots below the first truss had been allowed to develop Three different spacings between the rows were used The greatest yield per unit area was obtained from single-stemmed plants at the two closest spacings, namely, 2 ft and 3 ft, although multistemmed plants at 3 ft and 4 ft spacings had the greatest mean weight of individual fruit No treatment had any effect on weight per unit area of early fruit

A review of the literature on spacing of tomato plants in commercial cultivation, included in the report, shows that there is no simple answer to the question of optimal planting density for maximum yield It is thought that this may be because insufficient attention has been given to possible interactions between planting density and watering and manuring The study of the composition of the tomato fruit has been continued by the Chemistry Department, especially in relation to variety and state of ripeness of the fruit, with special reference to fruit quality and ripening disorders. It was concluded that the latter, evident by their effects on the outer fruit wall, were also related to the composition of the inner portion of the fruit Further investigations were made of the changes during ripening The acidity in the wall increased from the green stage to the first appearance of yellow pigmentation, but there was no consistent trend as ripening proceeded This was in contrast to the situation in the inner portion of the fruit, where acidity decreased and sugars (mainly glucose and fructose) increased The concentration of soluble solids in the expressed sap of the tomato varies considerably in relation to fruit quality and variety These investigations will be facilitated by the demonstration that measurement of refractive index by a simple hand refractometer gives a reliable indication of total dissolved solids

Work on urea–formaldehyde compounds as slow-acting nitrogenous fertilizers has been concluded, and a report gives the relative merits of the several compounds tested Liquid feeding of tomatoes is of considerable topical interest, especially in connexion with automatic irrigation, and research on this problem has been resumed Magnesium deficiency in glasshouse tomatoes is common, and preliminary results indicate that foliar sprays containing magnesium are more effective than soil treatments in maintaining normal leaf colour The plant-breeding programme is concerned mainly with improvements of tomato, cucumber and lettuce

---

* Glasshouse Crops Research Institute Annual Report 1957 Pp 161 (Littlehampton Glasshouse Crops Research Institute, 1958) 10s

The investigations on *Didymella* stem rot of tomato have been continued by the Plant Pathology Department, which is also concerned with powdery mildew of cucumber and wilt disease of carnation as well as mushroom diseases Some experiments were carried out on chemotherapeutic control of tobacco mosaic virus in the tomato, but it was concluded that this approach is not promising Although insecticides properly applied should give adequate control of white fly, there are sometimes risks of chemical injury to plants, and for this reason interest has been revived in the method of biological control by wasp parasites The Entomology Department has begun a series of studies on the effects of environmental factors on the fecundity and development of white fly and on the host/parasite balance Other investigations by this Department include mushroom pests and the red spider mite The Crop Protection Department is concerned with the control of mildew of chrysanthemums and aphids on lettuce and with the residual toxicity of certain sprays

E C HUMPHRIES

RADIOLOGICAL HAZARDS TO PATIENTS

AT the end of 1956, the Secretary of State for Scotland and the Minister of Health appointed a committee "to review the present practice in diagnostic radiology and the use of radiotherapy in non-malignant conditions, having regard to the report of the Committee on the Hazards to Man of Nuclear and Allied Radiations"

This committee, under the chairmanship of Lord Adrian, has now produced an interim report (Ministry of Health, Department of Health for Scotland Radiological Hazards to Patients Interim Report of the Committee Pp 22 London H M Stationery Office, 1959 1*s* 3*d* net) for the one completed part of its survey, namely, the use of X-rays for mass miniature radiography The conclusion is drawn that, when properly conducted, examinations by this method make a negligible contribution to the total radiation to which the population is daily exposed Even on the most pessimistic assumptions, the indefinite continuation of mass miniature radiography at the present rate could add no more than 20 cases of leukæmia to the annual incidence of 2,500 cases in Great Britain, it is also possible that it would produce no additional cases at all The gonad doses, which determine the long-range genetical damage, have been found to be even smaller than previously estimated These very small somatic and genetical risks have to be considered in relation to the undoubtedly large benefits of mass miniature radiography to the health of the population In 1957, these examinations led to the discovery of nearly 18,000 cases of pulmonary tuberculosis and some 63,000 other abnormalities, which included lung cancer, heart disease and pneumoconiosis For children and pregnant women, mass miniature radiography is not recommended and should be replaced by normal radiographic procedures with strict limitation of the field to the chest Some general principles are also given for reducing unnecessary exposure in other forms of diagnostic radiology, in particular fluoroscopy, but the survey of this area is not yet completed

There is one statement in the introduction (paragraph 10) which may give rise to serious misunderstandings It is stated, correctly, that a dose of radiation which would double the present mutation-rate would cause perceptible damage to the population, and that this dose is estimated to lie between 10 and 100 r per generation It is also correct to say that at present the dose due to medical radiology does not exceed 3 rads per generation But it is only for the sake of convenience that genetical damage is usually estimated in terms of the 'doubling dose' There is no lower threshold to the genetical effects of ionizing radiation, and serious genetical damage will be produced already by doses which are far below the doubling dose In fact, the report of the Medical Research Council came to the conclusion that, from the point of view of genetical hazards, "the upper limit, which future knowledge may set to the total dose of extra radiation which may be received by the population as a whole, is not likely to be more than twice the dose which is already received from the natural background, the recommended figure may indeed be appreciably lower than this" On this evidence, the danger limit has already been reached or even exceeded in countries where X-rays are used extensively for medical purposes Against this damage to future generations we must, however, set the benefit to the present one and, although all means must be used to cut down avoidable exposure to radiation, a high amount of exposure will remain unavoidable if the present standards of medical service are to be maintained

FEEDING THE HUNGRY

THE practical way to wage war on want was the theme of an outstanding address at St John's College, Annapolis, Maryland, on April 9 by Mr Gerard Piel, publisher of *The Scientific American* Following an account of the way in which science has given man unlimited power and opportunities to change the material conditions of life, Piel shows how it is now possible to bring the elimination of want within the reach not only of the present generation but also of all future generations Want is no longer a challenge to technology, but to economics and politics, it is a social problem Thanks principally to the control of mortality, the under-privileged peoples are living longer and feeling well enough to do something about their plight These aroused people are still extracting the irreplaceable resources of their lands to feed the voracious appetite for raw materials of Western peoples At present the

United States imports from overseas iron ore, bauxite, oil and a host of commodities in greater volume than ever before. In some American sectors the technology is perilously dependent upon riches supplied so cheaply. The goodwill and compliance of the natives have immediate relevance to the American price structure.

It is impossible to stop at the churlish counsel that the Colonials should reduce their numbers. Their population is rising because the modicum of sanitation introduced to protect white Colonials in their midst has reduced their rate of mortality as well. Their numbers are increasing, according to United Nations studies, at a rate that exceeds 1 per cent per annum. Since the end of the Second World War their material condition has been in corresponding decline , their calorie intake has actually fallen.

To offset the claim of population growth and reverse the decline in their condition, they must increase their production at a rate greater than their population growth. The larger the differential, the faster will their lot improve. Such an objective is not only technologically but also politically and economically feasible. American industrial growth has averaged 5 per cent over long periods , it has reached 8 per cent under intense pressure. The growth of agricultural output has correspondingly proceeded at the rate of 2 per cent in normal times. In response to the economic cycle and to controlled prices and other regulatory devices, it fluctuates over an even wider range. The present curtailment of grain production in the United States represents 200,000 tons, which approximates to the calorie deficit for the underfed portion of the world population.

About 500 billion dollars over the next fifty years would secure an average gain per annum of 2 per cent in industrial production and a corresponding increase in agricultural output in non-Western areas. Not all the 500 billion dollars would have to be supplied from outside. At about the halfway point the new industrial centres would begin to generate some additional capacity of their own.

Bed-rock investments, however, are not particularly attractive to the world's capital market. These involve such elementary public utilities as communication systems, including highways as well as railroads, and dams for flood control and irrigation. Investments in such projects call for the kind of funds now written off on armaments. A long-range view should be taken in looking for return on investment.

Western technology is specially qualified to contribute to the soaring demand for electrical energy which will attend industrialization programmes. But the demand for huge volumes of energy, heavy equipment and big investment would not come at the outset. First, there is need for planning and, then, engineering. Many of the early gains in these areas would be achieved with very little expenditure on capital goods. The first requirement is for brains and knowledge.

An example of what can be accomplished is furnished by Mexico. For the past twenty years the Rockefeller Foundation has been working with the Ministry of Agriculture and Animal Husbandry of Mexico. At a cost of less than 2 million dollars a year, American agronomists have been supplied to Mexico, and young Mexicans have been trained in the agricultural sciences. In this period, the food production of the country has risen 80 per cent. The gains have been achieved by improved yields of Mexico's own staple crops, the development of new varieties of wheat and potatoes and the establishment of something like the American county-agent system for farmer education. Not a single tractor or fertilizer plant is in the expense account , the money has been spent on the intangibles of information, education and expert consultation. The 4 per cent per annum gain safely exceeds the 3 per cent increase in population and has brought an improvement in the people's diet which is already showing up in vital statistics.

Somewhere in American material and intellectual resources the capacity to expand on this precedent could be found. If a beginning could be made, it would soon be possible to have additional wealth and brains available for the task as a result of the attenuation of the arms race on which prosperity now rests so heavily and insecurely.

SYMPATHETIC POSTGANGLIONIC MECHANISM

By Prof. J. H. BURN, F.R.S., and M. J. RAND
Department of Pharmacology, University of Oxford

DURING recent years it has been demonstrated that acetylcholine exerts an action in various organs similar to that of sympathetic stimulation. Since this action is seen in the presence of atropine and is also exerted by nicotine, it follows that the action is not a muscarinic but is a nicotinic action. An example of this action is the contraction of the arrectores pili muscles in the skin of the cat's tail. This was first described by Brucke[1] for acetylcholine, and a few years later by Coon and Rothman[2] for nicotine. Most of the hair was removed from the cat's tail except for a few tufts, and acetylcholine or nicotine was injected into the skin at the base of the tufts. Pilo-erection was then observed. Normally the pilomotor muscles are caused to contract by sympathetic stimulation, and they also contract after the intravenous injection of adrenaline or noradrenaline. Other examples of sympathomimetic effects caused by acetylcholine or by nicotine in the presence of atropine are the relaxation of the isolated intestine of the kitten by nicotine[3] , the acceleration of the isolated atria of the rabbit[4] and the constriction of the vessels of the perfused rabbit ear by acetylcholine and by nicotine[5], the contraction of the isolated nictitating membrane of the cat by nicotine[6]. de Burgh Daly and Scott (unpublished work) have observed that acetylcholine injected into the splenic artery during perfusion of the spleen with blood caused contraction of the spleen. We are grateful to them for allowing us to quote this result.

These nicotine-like effects of acetylcholine, exerted at sites peripheral to sympathetic ganglia, thus resemble the effects of sympathetic stimulation, they are not seen in preparations from animals treated with reserpine. Tissues innervated by sympathetic nerves were found by Schmiterlow[7] and by Euler and Purkhold[8] to contain noradrenaline together with a much smaller amount of adrenaline. After treatment of rabbits with reserpine, the noradrenaline which can be extracted from the heart disappears[9]. Similarly after treatment with reserpine, the noradrenaline disappears from the aorta of the dog and of the rabbit, from the skin of the rabbit's ear and from the skin of the cat's tail, from the cat's spleen and from the iris of the cat's eye[10].

The nicotine-like actions of acetylcholine are also lost when the sympathetic fibres degenerate, and this degeneration is also accompanied by a loss of the noradrenaline which can be extracted from the organ[8,10b].

The conclusion may therefore be drawn that the nicotine-like actions of acetylcholine which have been described are due to the release of noradrenaline (possibly with adrenaline also) from the organ.

At present we are uncertain of the location of the noradrenaline in the organ. v. Euler[11] believes that it is contained within the postganglionic fibres, calculating that the amount may be 3–30 mgm./gm. This is one thousand times more than that in postganglionic fibres before they reach the organ. This amount is only of the order of 15 μgm./gm. The disappearance of the noradrenaline after degeneration of the nerves is readily explained if it is present in the nerves.

There is some evidence, which as yet is only suggestive, that the noradrenaline and adrenaline in the organs might be present in cells containing chromaffin granules. Such cells have been described in human skin by Adams-Ray and Nordenstam[12], and also by Burch and Phillips[13]. They have been found in the skin of the rabbit's ear, in the skin of the cat's tail and in the nictitating membrane. The chromaffin granules are greatly reduced or disappear in the tissues of animals treated with reserpine, or in tissues in which the sympathetic fibres have degenerated[10a,c]. Thus it is possible that the nicotine-like actions of acetylcholine are due to the release of noradrenaline and adrenaline from cells containing chromaffin granules. However, Muscholl and Vogt[14] have found that reserpine depletes the noradrenaline stores in the sympathetic neurones more readily than those in chromaffin cells.

Tyramine is a sympathomimetic amine which ceases to act after degeneration of the sympathetic fibres[15]. Its pressor action is also absent in the cat previously treated with reserpine[16]. The conclusion may be drawn that tyramine exerts its action by liberating noradrenaline and adrenaline from the store in the organ. Since an infusion of noradrenaline into the vein of a cat or into the blood perfusing the hind-leg of a dog increases the pressor and constrictor action of tyramine, or restores it when it is absent due to previous treatment with reserpine, it appears that the store of noradrenaline in the organ can be increased by taking up noradrenaline from the blood stream[17].

The effect of sympathetic stimulation also is increased as a result of an infusion of noradrenaline. If the volume of one hind-leg of a dog is recorded in experiments in which the lumbar sympathetic chain is stimulated, then, atropine having been given, the threshold strength of stimulus for causing vasoconstriction in the hind-leg can be determined. Following an infusion of noradrenaline, the total amount given to the dog being 0.2–1.0 mgm. in the course of 20 min., the threshold has been observed to fall to a mean of 40 per cent of its previous value. In experiments in which the dog's hind-leg has been perfused it has been observed that the effect of a given sympathetic stimulus was greatly increased. These observations indicate that the efficiency of sympathetic stimulation depends on the amount of noradrenaline in the neighbourhood of the nerve endings. This may be taken up from the blood into the nerve endings themselves or into chromaffin cells; one of the functions of the noradrenaline secreted by the adrenal medulla may be to fill up this store.

We have now considered evidence that the nicotine-like actions of acetylcholine are due to the release of noradrenaline from a store near the sympathetic nerve endings; we have seen that this store can take up noradrenaline which is circulating in the blood, and we have seen that the effect of sympathetic stimulation depends on the size of this store. We now turn to the sympathetic impulses themselves.

When a cat is treated with reserpine with the result that the stores of noradrenaline and of adrenaline are depleted, the effect of tyramine on the nictitating membrane is completely absent, but stimulation of the postganglionic sympathetic fibres still causes a contraction. The threshold strength for this effect is greater than the threshold in the normal cat. We have found that the contraction produced is augmented by eserine and is abolished by atropine, and the contraction must therefore be due to the release of acetylcholine from the sympathetic fibres. The presence of cholinergic fibres in the sympathetic supply to the nictitating membrane was suggested by Bacq and Fredericq[18]. Recent work shows that the presence of cholinergic fibres is still more widespread. Thus Gillespie and Mackenna[19] have found that when a rabbit is treated with reserpine, the isolated colon is caused to contract by sympathetic stimulation instead of to relax, and that the contraction is abolished by atropine. They concluded that cholinergic fibres are present in the sympathetic supply.

Huković[20], working in this Department, has made an isolated preparation of rabbit atria with the sympathetic nerves attached; when the sympathetic fibres from the stellate ganglion were stimulated the rate and amplitude of the atrial beat increased. If the rabbit was treated beforehand with reserpine some preparations responded to sympathetic stimulation by inhibition, the inhibitor effect being increased by eserine and abolished by atropine. This result suggests that cholinergic fibres are present in the sympathetic supply from the stellate ganglion to the atria.

Observations have also been made on the cat spleen, recording the changes in volume of the spleen by a plethysmograph. The nerves were separated from the splenic artery near the beginning of the artery. Stimulation caused contraction of the spleen which was unaffected by atropine. When the cat was treated beforehand with reserpine, it was found that in some preparations acetylcholine caused a dilatation of the spleen, and that stimulation of the nerves was also followed by dilatation. This dilatation was increased in the presence of eserine and abolished by atropine. Thus the splenic nerves also contain cholinergic fibres. Observations have also been made on the virgin cat uterus, recording its contractions *in situ* under chloralose anæsthesia. When the hypogastric nerves were stimulated, inhibition followed. When the cat was treated beforehand with reserpine, stimulation of the hypogastric nerves caused a small contraction which was greater in the presence of eserine and which was abolished by atropine. The evidence suggests that the hypogastric nerves contain cholinergic fibres.

The observations that the nicotine-like effects of acetylcholine resemble those of sympathetic stimulation, and that these effects are exerted by the release of noradrenaline (or adrenaline), must now be put side by side with the evidence of the existence of cholinergic fibres in postganglionic sympathetic fibres in various places where they were not suspected. It then appears that such cholinergic fibres may be adrenergic in their effect, because the acetylcholine which they liberate will cause the discharge of noradrenaline or of adrenaline from the peripheral store. The stimulation of such fibres can in theory have two effects, one, normally much the smaller, due to the direct action of the acetylcholine released, an action which is sensitive to atropine, and the other, normally much the greater, due to the released acetylcholine causing a discharge of noradrenaline from the store, a nicotine-like action not affected by atropine. This double effect may actually be present in the nictitating membrane, where the response to postganglionic stimulation in the normal cat is slightly diminished by atropine, for example to about 80 per cent of its initial size.

Such a double effect might explain the response to stimulation of the sympathetic supply to the muscles of the dog's hind-leg, where Burn[15b] observed that a stimulus for 3 sec. caused dilatation, while the same stimulus applied for 30 sec. caused in the main constriction. A double effect is possible only when acetylcholine has a direct muscarinic action of its own. Thus in the cat treated with reserpine, stimulation of the sympathetic fibres has no pilomotor effect in the tail. The accumulated evidence thus requires consideration of a new possibility. The adrenergic sympathetic fibre has been thought of as liberating noradrenaline in the same way as cholinergic fibres liberate acetylcholine. However, cholinergic fibres, which seem widespread in the postganglionic sympathetic supply, may liberate noradrenaline from the store at the nerve endings, and thus be adrenergic in effect.

In this account we have kept open the possibility that noradrenaline may not always be the main component of the peripheral store and that around some sympathetic nerve endings, in the virgin cat uterus, for example, adrenaline may be more important. We have no evidence on this as yet. We may also recall that Pines[21] has described the chromaffin cells in sympathetic ganglia and has given a detailed account of his findings that they are innervated.

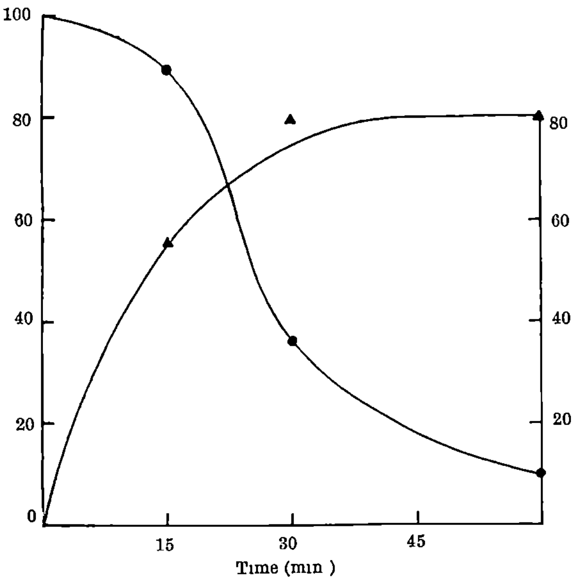
PROTEIN BIOSYNTHESIS AND OXIDATIVE PHOSPHORYLATION IN ISOLATED RAT LIVER MITOCHONDRIA

By P. J. REIS, J. L. COOTE and T. S. WORK

National Institute for Medical Research, Mill Hill, London, N.W.7

ELECTRON microscopy combined with differential centrifugation of sucrose homogenates has shown that liver parenchymal cells have a complex cytoplasmic structure[1]. After intravenous injection of amino-acids labelled with carbon-14 the proteins of the subcellular cytoplasmic structures of these cells become labelled at different rates. In both rats and guinea pigs the liver microsomal fraction is labelled considerably more rapidly than the mitochondrial material. Labelling is particularly rapid in the ribonucleoprotein fraction of the microsomes[2]. The suggestion has been made that protein synthesis takes place mainly in the microsomal ribonucleoprotein fraction and that mitochondria acquire radioactive protein from the microsomal fraction. The present results and those of Bates *et al.*[3] indicate that rat liver mitochondria are capable of independent protein synthesis.

Mitochondria were isolated from rat liver by differential centrifugation of a 1 : 4 sucrose homogenate. Best results were obtained with a mixture containing sucrose (0·3 *M*), versene (0·002 *M*) and nicotinamide (0·03 *M*); this mixture will be referred to as SVN. The fraction collected between 1,000 and 6,000*g* was washed by four successive cycles of re-suspension in and precipitation from SVN. Washed mitochondria in a mixture of sucrose (0·15 *M*), phosphate (0·01 *M*), tris buffer (0·02 *M*), $MgSO_4$ (0·008 *M*) and sufficient KCl to maintain tonicity showed negligible incorporation of labelled amino-acids into mitochondrial protein during aerobic incubations. The mitochondrial protein was obtained by precipitation with trichloroacetic acid and treatment to remove adsorbed amino-acids, ribonucleic acid and lipids. Incorporation was stimulated by the addition of either succinate or α-ketoglutarate,



Ordinates: left, per cent of initial rate of oxidative phosphorylation; right, counts per min.

Fig. 1. Dependence of incorporation of amino-acid into mitochondrial protein upon oxidative phosphorylation. Washed mitochondria from about 3 gm. rat liver were suspended in 5.5 ml. of medium of the following composition: *tris* buffer (0.05 *M*), potassium phosphate (0.01 *M*), potassium succinate (0.01 *M*), magnesium sulphate (0.008 *M*), potassium chloride (0.065 *M*), versene (0.0013 *M*), nicotinamide (0.02 *M*), ^{14}C-*Chlorella* protein hydrolysate (5 μc.), sucrose (0.11 *M*), added as 2.0 ml. boiled cell sap. Incubations were at 30°, in an atmosphere of oxygen. Oxidative phosphorylation was measured essentially as described by Slater (ref. 10), glucose-6-phosphate was estimated by the method of Kornberg and Horecker (ref. 11)

together with cell sap. At an early stage in the investigation it was found that, contrary to the report of Greengard[4], boiled cell sap was just as effective as whole cell sap. Both the rate and the duration of amino-acid incorporation into mitochondrial protein could be increased by adding progressively larger quantities of boiled cell sap. The incorporation reaction was stimulated by incubation in oxygen instead of air and almost completely inhibited by incubation in nitrogen or by the addition of dinitrophenol or cyanide. The behaviour of the incorporation reaction towards inhibitors indicated that incorporation was probably linked to oxidative phosphorylation; amino-acid incorporation and oxidative phosphorylation were accordingly measured in the same mitochondrial preparation. The results (Fig. 1) showed that as the rate of oxidative phosphorylation declined, the rate of incorporation declined in a similar manner.

The duration of oxidative phosphorylation in isolated rat liver mitochondria is notoriously sensitive to conditions of incubation[5]. Calculation of the amount of adenine nucleotide in boiled cell sap indicated that the final concentration of nucleotides in the incubation mixture was below that usually required to maintain mitochondrial structure and oxidative phosphorylation. Accordingly, the boiled cell sap was supplemented with 0.004 *M* adenosine monophosphate and 0.0005 *M* diphosphopyridine nucleotide. Mitochondria incubated under these conditions were able to maintain oxidative phosphorylation and incorporation of labelled amino-acids for 2 hr. at 30°, although the rate of incorporation was falling off after 1 hr. The work of Siekevitz and Potter[5] and of Pressman[6] indicates that the balance of nucleotides and of inorganic phosphate inside the mitochondrial membrane is best maintained when an acceptor for energy-rich phosphate bonds is present in the medium. Thus when the system was further supplemented with hexokinase and glucose, incorporation of amino-acids into mitochondrial protein could be maintained at, or near, a linear rate for 2 hr. at 30°. Incubations have not been carried beyond 2 hr.

Mitochondria are composed of a structurally complex double membrane within which are disposed various soluble but rather firmly bound enzymes. It was found that in the presence of adenosine monophosphate and diphosphopyridine nucleotide, both with and without hexokinase, the insoluble proteins of the mitochondria were effectively labelled either by a mixture of amino-acids labelled with carbon-14 or by a single labelled amino-acid (phenylalanine). Soluble protein was not, however, significantly labelled even after 2 hr. at 30° (soluble protein was released either by the butanol method of Morton[7] or by the extraction of an acetone-dried powder of mitochondria with phosphate buffer). Increase in the amount of boiled cell sap, with maintenance of the adenosine monophosphate and diphosphopyridine nucleotide concentration at the level given above, resulted in a substantial improvement in the efficiency of labelling of the insoluble protein and produced slight activity in the soluble protein. Boiled cell sap contains substantial quantities of amino-acids (80 μgm. amino-nitrogen/ml.) and it was found that these could be replaced by a complete mixture of 20 amino-acids. It was found that, as the concentration of these amino-acids in the incubation medium was progressively increased, the incorporation into insoluble protein rose to a maximum at an amino-acid concentration of 30–40 μ*M*/ml. The incorporation into soluble protein was initially low; but as amino-acid concentration was increased, the radioactivity of the soluble protein continued to rise in an approximately linear manner. Thus the incorporation into soluble protein of the mitochondria progressively becomes a greater proportion of the total incorporation, as amino-acid concentration is increased. The most likely explanation of these results is that there are relatively few sites of protein synthesis in mitochondria (templates?). When these sites become saturated with incoming radioactive amino-acid further increase in amino-acid concentration (of fixed specific radioactivity) will not result in any further increase in radioactivity of insoluble protein. Increased amino-acid concentration will result, however, in a progressively greater tendency for newly synthesized protein to be displaced from the sites of synthesis into the intracisternal spaces so that there will continue to be a progressive increase in the rate of accumulation of radioactivity in soluble protein.

There is no doubt that the amino-acid incorporation reaction measured in these experiments is truly intramitochondrial and is not due to adherent microsomes. First, incorporation is not abolished by thorough washing of the mitochondria as described previously (this washing procedure has been shown to remove at least 95 per cent of microsomes labelled with carbon-14 added to the sedimented mitochondria); secondly, the incorporation reaction does not require fresh cell sap with its supply of soluble ribonucleic acid[8] and 'amino-acid activating' enzymes; thirdly, the incorporation is much more prolonged than that obtained with microsomes *in vitro*; and fourthly, the incorporation is quite unaffected by addition of ribonuclease to the incubation mixture This does not, however, prove that ribonucleic acid plays no part in amino-acid incorporation since we have found that, even after 2 hr at 30° in the presence of ribonuclease, mitochondria retain about 70 per cent of their ribonucleic acid (originally 17 µgm /mgm mitochondrial protein) Indeed, the incorporation reaction in mitochondria may have closely similar characteristics to that occurring in microsomes since we have found that an extract of mitochondria will catalyse an amino-acid-dependent exchange between adenosine triphosphate and radioactive pyrophosphate (Table 1)

Table 1 AMINO-ACID ACTIVATION IN RAT LIVER MITOCHONDRIA

Extract of mitochondria prepared from	c p m per µmole adenosine triphosphate		
	No amino-acids	Plus amino-acids	Increment due to amino-acids
0 6 gm Liver	1,810	2,400	580
1 2 gm Liver	3,060	4,280	1,220

Mitochondria were isolated and washed four times, an acetone powder was prepared and extracted with 0 1 M tris buffer, pH 7 6 This soluble extract was incubated with tris buffer, pH 7 6, 100 µmoles, magnesium chloride, 2 µmoles, adenosine triphosphate, 5 µmoles, a mixture of 12 amino-acids, 2 µmoles of each, ^{32}P-pyrophosphate, about 2 µmoles, 150,000 c p m , vol 1 ml Incubated for 15 min , 37°

Before one can be convinced that the amino-acid incorporation observed in these experiments represents true synthesis of protein, it would be necessary to demonstrate synthesis of a specific protein In this regard the synthesis of cytochrome *c* has already been demonstrated in isolated mitochondria from rat liver[3] and calf heart[9] The presence of numerous enzymes within mitochondria suggests that this *in vitro* system should be a valuable tool in further studies on protein biosynthesis Work has already been initiated along these lines

STRUCTURE OF A MELANOCYTE-STIMULATING HORMONE FROM THE HUMAN PITUITARY GLAND

By DR. J. IEUAN HARRIS*

Department of Biochemistry, University of Cambridge, and the Biological Laboratories, Harvard University

A MELANOCYTE-STIMULATING substance from human pituitary glands has recently been isolated in pure form by ion-exchange chromatography[1] It has been shown to be a slightly basic polypeptide which migrates as a single substance when submitted to ionophoresis on paper in pyridine-acetic acid buffers at pH's of 3 6 and 6 5

The amino-acid sequence of the polypeptide hormone has been investigated by methods similar to those described[2,3] for the elucidation of the structure of α-melanocyte-stimulating hormone from pig pituitary glands The particular methods which have been used were to a great extent determined by the limited amount of the substance (4–5 mgm) which was available for study

Specific colour tests[4] carried out on the intact polypeptide showed that it contained tryptophan, tyrosine, histidine and arginine , and when a total acid hydrolysate was submitted to qualitative chromatographic analysis on paper the following amino-acids were shown to be present alanine, arginine, aspartic acid, glutamic acid, glycine, histidine, lysine, methionine, phenylalanine, proline, serine, and tyrosine

A sample of the hormone (2 5 mgm) was allowed to react with chymotrypsin (0 1 mgm) in 0 05 M ammonium bicarbonate (2 ml) at pH 8 0–8 5 and 37° for 10 hr When the product was fractionated by ionophoresis on paper in pyridine-acetic acid (pH 6 5) at 40 volts/cm for 2 hr it was resolved into five peptide fragments

Table 1 AMINO-ACID COMPOSITION AND C-TERMINAL AMINO-ACIDS OF PEPTIDES PRODUCED BY CHYMOTRYPTIC HYDROLYSIS OF HUMAN β-MELANOCYTE-STIMULATING HORMONE

Peptide	Amino-acid composition	C-terminal group
C_1	Ala,Asp,Glu,Gly,Lys,Pro,Tyr	Tyr
C_2	Arg,Asp,Gly,Lys,Pro,Ser,Try	Asp
C_3	Arg,Glu,His,Met,Phe	Phe
C_5	Asp,Gly,Lys,Pro,Ser	Asp
C_6	Arg,Try	Try

The amino-acid compositions of these five peptides (C_1, C_2, C_3, C_5 and C_6) were determined by means of specific colour tests[4], and by paper chromatographic analysis of their total acid hydrolysates , the corresponding C-terminal amino-acids were determined by means of carboxypeptidase[5] The results, summarized in Table 1, showed that the human melanocyte-stimulating hormone was of the 'β-melanocyte-stimulating hormone' type, and that it was closely related in terms of chemical structure to β-melanocyte-stimulating hormone[6,7] from pig pituitary glands Thus, peptides C_2, C_3, C_5 and C_6 were found to have the same electrophoretic mobilities at pH 3 5 and pH 6 5, and the same qualitative amino-acid compositions (with the exception of C_3, which contained arginine instead of lysine), as the corresponding peptide fragments[6] derived from pig β-melanocyte-stimulating hormone by digestion with chymotrypsin Peptide C_1, on the other hand, differed from the corresponding peptide fragment from pig β-melanocyte-stimulating hormone, both in electrophoretic and chromatographic behaviour, and in amino-acid composition, although the C-terminal amino-acid, tyrosine, and four of the other constituent amino-acids—aspartic acid, glutamic acid, glycine and proline—were common to both peptide fragments

---

* Member of the Scientific Staff of the Medical Research Council (at present Research Fellow in Biology, Harvard University, Cambridge, Mass)

The presence of lysine suggested that C_1 would be susceptible to the action of trypsin It was therefore allowed to react with trypsin for 4 hr at 37° , when the product of reaction was fractionated by ionophoresis at *p*H 6 5 it was resolved into two major (C_1TA_1, C_1TB_1) and two minor (C_1TA_2, C_1TB_2) components Their qualitative amino-acid compositions were determined and are given in Table 2

Table 2 Amino-acid Composition and C-terminal Amino-acids of Peptides produced by Tryptic Hydrolysis of Peptide C_1 (Table 1)

Peptide	Amino-acid composition	C-terminal group
C_1 TA_1	Asp,Glu,Gly,Lys,Pro,Tyr	Tyr
TB_1	Ala,Glu,Lys	Lys
TA_2	Asp,Glu,Gly,Pro,Tyr	Tyr
TB_2	Lys	—

One of the minor peptide components, C_1TA_2, appeared to be identical with the N-terminal peptide, Asp Glu Gly Pro Tyr , in pig β-melanocyte-stimulating hormone[6], as judged by its electrophoretic mobility at *p*H 6 5, R_F in butanol-acetic acid-water (4 1 5), amino-acid composition, and C-terminal group The two major peptide components, C_1TA_1 and C_1TB_1, were both found to contain lysine , and the fact that a significant amount of free lysine (C_1TB_2) was also formed in the tryptic reaction suggested that the parent molecule, C_1, contained a Lys Lys bond, and that it was the N-terminal peptide (Ala,.Glu) Lys Lys (Asp Glu Gly Pro) Tyr in the human β-melanocyte-stimulating hormone molecule

After their homogeneity had been established both by electrophoretic and chromatographic analysis, peptides TA_1, TA_2, TB_1 and C_5 were submitted to partial acid hydrolysis (12 *N* hydrochloric acid, for 3–6 days at 37°) , peptide C_3 was hydrolysed with subtilisin[8] (12 hr at 37°) The respective products of reaction were fractionated by ionophoresis on paper and were characterized by the procedures which have been described previously[3,6] The results are summarized in Table 3

Peptide C_2 was shown to give additional amounts of C_5 and C_6 when it was redigested with chymotrypsin, showing that C_5 and C_6 formed contiguous sequences in the molecule By means of carboxypeptidase, C_6 was shown to be a dipeptide containing arginine and tryptophan , in a similar manner aspartic acid was shown to be the C-terminal amino-acid in both C_2 and C_5, showing that these two peptides formed the C-terminal sequence, Arg Try (Gly,Ser,Pro, Lys) Asp, in human β-melanocyte-stimulating hormone (cf ref 6)

Although it was not found possible to undertake quantitative amino-acid and end-group analyses on the parent molecule, the results which have been obtained with peptide fragments derived from it by hydrolysis with chymotrypsin and trypsin nevertheless appear to be sufficient to establish that human β-melanocyte-stimulating hormone contains twenty-two amino-acid residues, and that they occur in the following sequence

Table 3 Peptides Identified in Partial Acid* (12 *N* Hydrochloric Acid, 37°) and Subtilisin† Hydrolysates

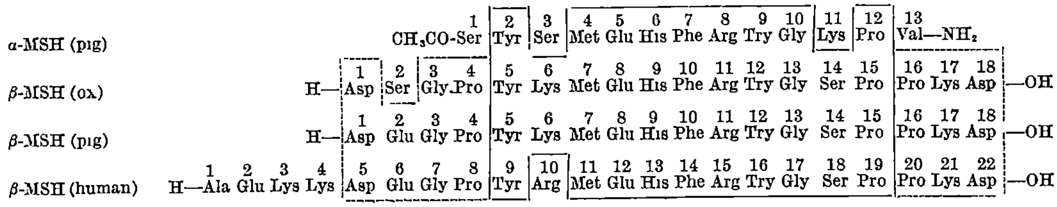
Peptide	Products of partial hydrolysis
*C_1TB_1	Ala Glu, Glu Lys
*C_1TA_1	Lys Asp, Lys Asp Glu, Glu Gly, Gly Pro Tyr
*C_5	Ser Pro, Ser Pro Pro, Ser Pro Pro Lys, Pro Pro Lys, Pro Lys, Lys Asp
†C_3	Arg Met, Arg Met Glu, Glu His, Glu His Phe

1 2 3 4 5 6 7 8 9 10 11
H— Ala Glu Lys Lys Asp Glu Gly Pro Tyr Arg Met
12 13 14 15 16 17 18 19 20 21 22
Glu His Phe Arg Try Gly Ser Pro Pro Lys Asp — OH

This appears to be the first of the polypeptide hormones from the human pituitary to be isolated in pure form and to be characterized in terms of its complete chemical structure The amino-acid sequences of human, pig[6,7] and ox[9] β-melanocyte-stimulating hormones and pig α-melanocyte-stimulating hormone[2,3] are compared in Fig 1

Although human β-melanocyte-stimulating hormone manifests a structural 'species' difference of the 'classical' type, namely, the replacement of a lysine residue (position 6 in pig and ox β-melanocyte-stimulating hormone) by arginine (position 10 in human β-melanocyte-stimulating hormone) in structurally related positions, the presence of the additional N-terminal tetrapeptide, Ala Glu Lys Lys, represents a hitherto unprecedented structural species variation among naturally occurring biologically active polypeptide and protein molecules of relatively low molecular weight (for example, vasopressins[10,11], corticotropins[12], insulins[13] and hypertensins[14,15])

Ox β-melanocyte-stimulating hormone[9] is found to differ from pig β-melanocyte-stimulating hormone only in position 2 (Fig 1), where the glutamic acid residue in the pig hormone is replaced by a serine residue in the ox hormone It is perhaps significant that the replacement of one amino-acid by another which is structurally unrelated to it occurs in a part of the molecule which does not appear to be specifically essential for its biological activity[3] (cf corticotropins[12]) Presumably genetical alterations which produce structural modifications of this type in essential parts of the molecule would result in the formation of molecules in which biological specificity was either modified or destroyed Consequently the fact that a lysine residue in the pig and ox hormones is replaced by the structurally related amino-acid, arginine, in the human hormone, and that the structural features common to all known β-melanocyte-stimulating hormones and corticotropins[12,16]



α-MSH (pig)

Fig 1 Amino-acid sequences of melanocyte-stimulating hormones from pig, ox and human pituitary glands MSH, melanocyte-stimulating hormone

remain intact, suggests that the amino-acids which occupy these key positions in β-melanocyte-stimulating hormone are directly associated with its biological activity in the *in vivo* environment in which it has been designed to function as a hormone

In α-melanocyte-stimulating hormone, on the other hand, there is an *interchange* of lysine and serine residues between positions 3 and 11 (Fig 1), which correspond to positions 6 and 14 in pig and ox β-melanocyte-stimulating hormones, and to positions 10 and 18 in human β-melanocyte-stimulating hormone This would suggest that factors other than the linear arrangement of amino-acid residues must be taken into consideration in relating structure to biological function in the living cell even in comparatively small peptide molecules which do not appear to possess any ordered secondary or tertiary structure in aqueous solution

I am indebted to Dr H B F Dixon for his generous gift of the sample of pure human melanocyte-stimulating hormone Most of the experimental work was carried out in the Division of Biochemistry of the Massachusetts Institute of Technology, and I am indebted to Dr Vernon Ingram for his kindness in placing the facilities of his laboratory at my disposal. GROWTH PATTERNS IN *NEUROSPORA*

A Biological Clock in *Neurospora*

MANY fungi produce alternating zones of different growth type in response to diurnal light-cycles and temperature-cycles, and in some cases the zonation will continue to be produced for a time in continuous darkness and at a constant temperature In 1953 Brandt[1] reported observation of zonation in the growth and conidia formation of *Neurospora crassa* mycelia in standard glass race-tubes maintained in constant darkness, humidity and temperature Inspection of Brandt's photographs suggested to us that the zones were formed with a frequency of approximately one a day, and we have tested the implication that there does occur in *Neurospora* a typical biological daily clock—that is, a rhythmic system with an innate circadian ('about a day') period which is relatively independent of the temperature (We are here adopting the suggestion (personal communication) of Prof F Halberg that the word 'circadian' obviates all the long-standing confusion inherent in the words diurnal, daily, 24-hr, as adjectives to describe the rhythms with which we are concerned)

Brandt reported that he obtained zonation in only one (No 21863, prolineless) strain of several that he examined, and that the zonation occurred on only one of the supplemented media ('Gray's') that would support growth of this strain Zonation occurred at constant temperature either in a 24-hr light–dark cycle, or in continuous darkness after a brief period of initial growth in white light Zonation does not develop if the mycelium is maintained in continuous white light, but we have found that it can develop in continuous red (carbon) light

In the experiments reported here the same strain and media as those used by Brandt were also used Freshly inoculated race-tubes were placed in a temperature-controlled cabinet containing a 14-watt cool-white fluorescent lamp About 40 hr later, when the mycelium was growing well, the white light was discontinued and a red lamp was turned on At this time and at 24 hr intervals thereafter the advance of the mycelial front was observed (in the red light) and marked on the race-tube When the growth had reached the end of the agar, the tube was removed from the growth cabinet and a densimeter device was used to measure relative density of the mycelium along its entire length The observed phenomenon consists of alternating zones of sparse and dense mycelium Preliminary experiments failed to reveal any significant difference in the linear growth increments in the 4-hr intervals throughout any 24-hr interval The distribution of mycelial density has accordingly been converted from its observed spatial scale to a temporal scale Regions of dense growth show up as minima on the densimeter graphs

Fig 1 illustrates the results so obtained from two typical race-tubes, one maintained at 31° C and the other at 24° C Table 1 summarizes more extensive data on the time-interval between successive minima on the densimeter graphs This interval, which is the period of the rhythm, is about 22 hr and is the same at the two temperatures

The zonation of *N crassa* thus is regulated by a rhythmic phenomenon which manifests the essential features of a biological clock[2] The rhythm has an innate free-running period which is close to 24 hr relatively independent of the temperature The rhythm can be entrained by a 24-hr light-cycle In addition to possessing these functional prerequisites of a good chronometer, the rhythm also possesses other features of typical circadian systems (1) The phase of the rhythm can be established by a single transition from light to dark, (2) as with many other plant rhythms, the manifestation of the rhythm is

destroyed by continuous white light We have not yet studied entrainment by temperature-cycles, or the transient[3] pattern following single light signals

The *Neurospora* system appears potentially valuable for an attack on the basic problem of the nature of the oscillations that constitute the circadian clock We do not interpret the presence or absence of zonation as a reflexion of the presence or absence of the clock, but rather as a coupling or uncoupling from the clock of the particular processes leading to zonation Thus, it may be necessary to find some other manifestation of the basic rhythm which is present even when there is no zonation before one can make all the intriguing analyses that seem potentially possible However, the possibility of genetic analysis, the feasibility of heterokaryon formation, and the fact that *Neurospora* can be grown on fully defined media are features which make the system uniquely useful For example, the pattern of zonation in a heterokaryon between two strains with a previously established 12-hr phase difference might resolve the question Is the clock oscillation a nuclear or a cytoplasmic feature ?

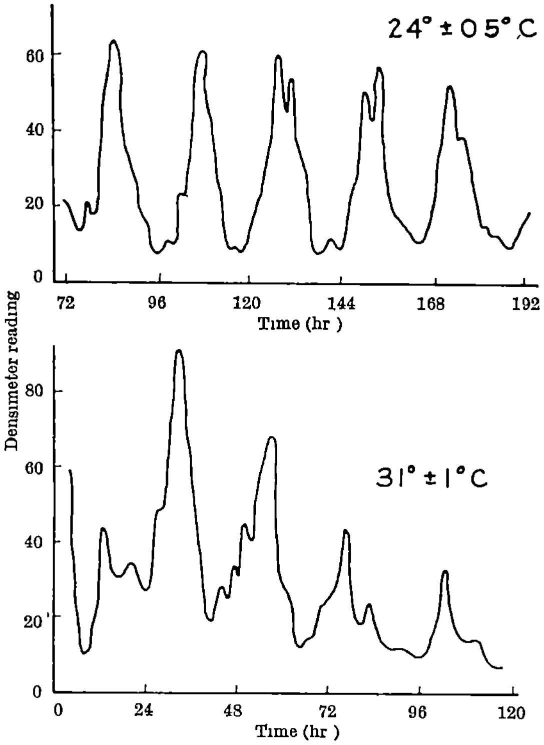

Fig 1 Zonation in *Neurospora* Zonation of the growth in a race-tube of a prolineless strain of *Neurospora* has been measured using a densimeter to record the relative density of mycelial growth The time-scale shown represents hours elapsed after transfer of the race-tubes from white light to dim red light as described in the text

Genetic Control of a Cyclic Growth Pattern in *Neurospora*

A STRAIN of *Neurospora* has been described which displays a daily cycle of growth morphology[1], and it has been demonstrated that this growth pattern reveals the presence in the organism of a temperature-independent biological clock[2] The cyclic growth pattern consists of alternating regions of dense and sparse mycelium Each dense region has a conspicuous tuft, or patch, of aerial growth on which orange macroconidia are produced The pattern was demonstrated by strain 21863*a*, a proline-requiring mutant, when grown in race-tubes of Gray's medium[1] Other strains grown in the same conditions produce a uniformly dense mycelium, and conidia formation occurs much later than in the tufts of 21863 This report concerns a study of the genetic control of this growth pattern The cyclic growth condition will be termed 'patch', and the symbol will be *pat* ('tuft' has already been used for another phenotypic character)

Strain 21863*a* was crossed to wild-type 74*A* Asci were dissected into ordered spore pairs Eight complete asci (all four spore pairs growing) were classified for mating type, proline requirement, and patch (Table 1) The cyclic growth pattern segregated 2 2 in every ascus, as did mating type and proline requirement Patch and proline requirement are controlled by separate genes which are not closely linked On the other hand, patch showed close linkage to mating type, in these eight asci there was no recombination between them

The mating type locus is in the left arm of linkage group I Failure to metabolize nitrate is determined by a gene (*n-nit*) in the right arm[3] The cross *pat a* × *n-nit A* was dissected, and thirteen complete asci were obtained Their classification is shown in Table 2 The results indicate the patch locus is in the left arm of linkage group I, proximal to mating type

Classification of the progeny of these crosses for patch was made in race-tubes of Gray's medium at 25° C , the tubes were in constant light for 24 hr , then transferred to constant dark for 2–3 days before scoring Tests in minimal medium[4] (supplemented

with proline) and in complete medium[5] were carried out in race-tubes in the same light and temperature conditions, but not all the *pat* segregants gave clear-cut cyclic growth patterns

Normally, growth began quickly on Gray's medium and extended 1–4 cm down the length of the race-tube after 24 hr However, six of the cultures had a lag period of about three days before any growth appeared These were the six proline-requiring *pat*+ segregants of the first cross (Table 1) There is thus a physiological interaction which might be described as partial suppression of *prol* by *pat* (though it could also be suppression by mating type gene *a*) Whether this interaction is related to the function of the biological clock is unknown (The lag period occurred only on Gray's medium , none of the cultures lagged on minimal medium plus proline or on complete medium)

Note Different patterns of second division segregation have been grouped together for brevity

The tests for proline requirement were made on plates containing the sugar sorbose , this causes growth to remain restricted to the spot of the inoculum, rather than spreading over the plate The use of sorbose medium allows as many as twenty-five growth tests to be performed on a single plate It was observed that some of the test colonies did not remain confined on the sorbose plates, but were expanding radially 5–10 mm per day The 'sorbose-escape' condition turned out to be characteristic of the patch segregants This was a consistent correlation , all 42 *pat* progeny from the two crosses escaped on sorbose, while all 42 *pat*+ progeny remained confined on sorbose There was no evidence of any cyclic pattern in the sorbose-escape colonies Sorbose-escape was achieved even on plates held in constant light, a condition in which the cyclic growth pattern is not observed on Gray's medium

The sorbose-escape classification demonstrates that the presence of the patch gene can be detected in a situation in which it is not visibly related to a biological clock It is possible that the patch gene is not directly involved in the function of the biological clock, but, rather, effects a growth habit which reveals an underlying clock However, this could only be determined conclusively by a demonstration of clock activity in a *pat*+ strain

This work was supported by a grant from the National Science Foundation I am grateful to Dr C S Pittendrigh and Dr V G Bruce, of Princeton University, for providing the strain 21863*a*

PROTHORACIC GLAND STIMULATION BY JUVENILE HORMONE EXTRACTS OF INSECTS

By DR LAWRENCE I GILBERT* and DR HOWARD A SCHNEIDERMAN

Department of Zoology, Cornell University, Ithaca, New York

THE juvenile hormone was first recognized as the agent which prevents maturation of young insects[1] A second role for this hormone, discovered shortly thereafter, was in egg development where, in many insects, it is necessary for yolk deposition[2] The present article describes what appears to be a third role for the juvenile hormone, namely, stimulation of the prothoracic glands This tropic action has hitherto been assigned either to a hormone secreted by the insect's brain[3] or occasionally to low temperature[4] Experiments were conducted on pupæ of a variety of giant silk moths of the family Saturniidae *Hyalophora cecropia*, *Samia cynthia*, *Antherea polyphemus* and *Callosamia promethea* Pupæ in two physiological states were employed as test objects (*a*) diapausing pupæ which ordinarily remain for months in the pupal stage without developing, (*b*) pupæ which were stored at 5–8° C for 5 months or more to activate their brains[3] Such 'well-chilled' pupæ ordinarily initiate development within two weeks of being placed at 25° C and emerge as adults $2\frac{1}{2}$–3 weeks later

---

* Present address Department of Biological Sciences, Northwestern University, Evanston, Illinois

In the first series of experiments, ether extracts were made of abdomens of male *H cecropia* moths following Williams's procedure[5] These ether extracts contain large amounts of juvenile hormone When the extracts were injected into diapausing *S cynthia* pupæ these moulted into second pupæ For our present purposes the fact that the second moult was pupal is unimportant since a moult of a pupa in the presence of juvenile hormone will almost invariably be pupal However, it is of interest that moulting occurred, for in our experience not one of thousands of diapausing *S cynthia* pupæ has ever initiated adult development without prior chilling Nevertheless, injection of 50 mgm or more of ether extract invariably caused these diapausing pupæ to moult precociously into second pupæ or pupal-adult intermediates (Table 1*A*) Pupæ that received less than 50 mgm failed to initiate adult development Similar results were obtained with both newly moulted and older diapausing pupæ of *H cecropia* and *A polyphemus* (Table 1*B*) In all cases, the ether extracts terminated pupal diapause

Table 1

(*A*) Moulting of unchilled seven-month-old diapausing *S cynthia* pupæ after injections of ether extracts*

Pupal weight (gm)	Mgm extract injected	Days to moult	Effect
1 60	50	27	Adult-like intermediate
1 56	100	13	Second pupa
1 83	100	17	Second pupa
1 65	150	13	Second pupa
1 80	150	23	Pupa-like intermediate

* Uninjected controls did not initiate development after 6 months

(*B*) Moulting of unchilled one-month-old diapausing pupæ of *H cecropia* and newly moulted diapausing pupæ of *H cecropia* and *A polyphemus* after injections of ether extracts

Pupal weight (gm)	Mgm extract injected	Days to moult	Effect
	H cecropia (one month)*		
4 65	100	—	No development after 6 months
5 30	200	23	Adult-like intermediate
5 25	250	13	Pupa-like intermediate
5 45	400	17	Pupa-like intermediate
5 40	400	—	No development after 6 months
5 46	450	23	Pupa-like intermediate
4 80	600	23	Pupa-like intermediate
4 75	600	23	Pupa-like intermediate

* Uninjected controls did not initiate development after 6 months

Hours after moulting	Mgm extract injected	Days to moult	Effect
	H cecropia (newly moulted)*		
4	100	—	No development after 6 months
12	300	19	Adult-like intermediate
36	100	31	Adult with few pupal characters
	A polyphemus (newly moulted)*		
Prepupa	200	—	No development after 3 months
1	200	55	Adult-like intermediate
6	200	23	Adult-like intermediate
10	150	19	Pupa-like intermediate
12	250	33	Pupa-like intermediate

* Uninjected controls did not initiate development after 3 months

In addition, when extracts were injected into 'well-chilled' pupæ they caused precocious moulting Thus, results of more than 800 injections into well-chilled pupæ of *S cynthia*, *C promethea*, *H cecropia* and *A polyphemus* disclosed that pupæ receiving more than 50 mgm of ether extract invariably moulted into second pupæ within 10–13 days These several results suggest that the juvenile hormone or some other constituent of the ether extracts stimulates moulting

To decide whether the ether extracts provoke moulting by stimulating the pupal brain or by directly stimulating the prothoracic glands, the following experiments were performed A series of diapausing *H cecropia* pupæ had their brains removed This placed the pupæ in permanent diapause and such brainless pupæ never spontaneously initiate adult development However, when three such brainless pupæ were injected with 200, 400 and 600 mgm of ether extract, the two which received the largest injections moulted into second pupæ while the third remained in diapause (Table 2) Similar results were obtained with brainless *S cynthia* pupæ (Table 2) From these experiments, it appears that large amounts of ether extract stimulate the prothoracic glands and so terminate pupal diapause

Table 2

(*A*) Moulting of brainless diapausing pupæ of *H cecropia* and *S cynthia* after injections of ether extracts

Pupal weight (gm)	Mgm extract injected	Days to moult	Effect
		H cecropia	
6 73	200	—	Never initiated development
5 53	400	41	Second pupa
6 10	600	32	Second pupa
		S cynthia	
1 90	100	13	Second pupa
3 21	250	15	Second pupa

An alternative explanation is that the ether extract contained some prothoracic gland hormone, ecdyson, and this reacted directly with the pupal tissues to initiate development This possibility was tested by injecting a large series of isolated pupal abdomens of *S cynthia* and *A polyphemus* with 80–300 mgm of ether extract None of these preparations ever initiated development, although many survived as long as four months. Moreover, repeated efforts to extract ecdyson from the ether extracts have failed These results seem to rule out the prothoracic gland hormone as the effective moult-promoting agent in the ether extracts Hence, it seems safe to conclude that something in the ether extracts stimulates the insect's prothoracic glands

To determine whether the factor which stimulated the prothoracic glands was the juvenile hormone itself, or some other substance, extracts in which juvenile hormone was concentrated 100–500-fold by various chemical procedures[6] were injected into chilled pupæ, diapausing pupæ and brainless pupæ As Table 3*A* reveals, the concentrated juvenile hormone preparations had potent prothoracic gland-stimulating activity Indeed, the prothoracic gland-stimulating factor was concentrated to about the same degree as the juvenile hormone by the chemical procedures we employed Moreover, when brainless diapausing pupæ were injected with huge amounts of ether extract from which juvenile hormone had been removed by countercurrent distribution, they failed to respond (Table 3*B*) In short, procedures which concentrate the juvenile hormone, concentrate the

Table 3

4 91	0 10	11	Second pupa

(*B*) Effect of juvenile hormone-free extracts on brainless diapausing *S cynthia* pupæ

Pupal weight (gm)	Mgm extract injected	Days to moult	Effect
3 20	180	—	Never initiated development
2 13	270	—	Never initiated development
2 19	300	—	Never initiated development
3 30	400	—	Never initiated development
2 80	450	—	Never initiated development

prothoracic gland-stimulating factor and procedures which remove juvenile hormone from extracts, also remove the prothoracic gland-stimulating factor These results indicate that the juvenile hormone or a molecule with similar chemical properties, perhaps brain hormone, is the effective agent in the extracts that triggers off the prothoracic glands Hence, we may conclude that either the juvenile hormone stimulates the prothoracic glands or the extract contains brain hormone in addition to juvenile hormone.

A final decision between these alternatives awaits tests with pure juvenile hormone preparations, but some insight is provided by two recent reports which were published when the present experiments were completed Williams[7] has announced that implantation of active corpora allata terminates diapause in brainless diapausing *H cecropia* pupæ This important result is consistent with the view that the juvenile hormone itself is the effective agent in our extracts that activates the prothoracic glands This prospect is made more attractive by the recent report of Kobayashi and Kerimura[8], which indicates that brain hormone extracted from the commercial silkworm has similar solubility properties to juvenile hormone Thus it seems possible that brain hormone is similar chemically to juvenile hormone, and it is perhaps not too surprising that both hormones can activate the prothoracic glands Whether or not the juvenile hormone actually functions in any immature insect to stimulate the prothoracic glands and cause moulting remains to be seen

We wish to express our thanks to Dr Berta Scharrer for her critical evaluation of this manuscript

Note added in proof Ichikawa, M , and Nishiitsutsuji-Uwo, J (*Biol Bull* , **116**, 88; 1959), have shown that the corpora allata of *Philosamia cynthia ricini* can induce moulting in brainless pupæ Their results indicate that, in addition to eliciting juvenile hormone, the corpora allata store neurosecretory material transported from the brain via the nervi corporis allati They conclude that implants of larval and adult corpora allata furnish two hormones controlling post-embryonic development, namely, juvenile hormone and a moult-inducing hormone derived from the protocerebrum (brain hormone) These results suggest that extracts of male *H cecropia* moths may contain brain hormone in addition to juvenile hormone

EVOKED POTENTIALS IN VISUAL CORTEX OF THE UNANÆSTHETIZED CAT

By GABRIEL HORN and JOHN BLUNDELL

Department of Anatomy, University of Cambridge, and Department of Neurology and Neurosurgery, McGill University and the Montreal Neurological Institute

RECENT work has indicated that when an animal 'attends' to a non-visual stimulus, photically evoked potentials in the visual pathway of the unanæsthetized cat are reduced[1] It was concluded from these and other studies[2] that this depression of evoked responses implies a reduction of the sensory inflow which, if it occurs " in all other sensory paths except the ones concerned with the object of attention, such an inhibitory mechanism might lead to the favouring of the attended object by the selective exclusion of incoming signals"[2] It is not clear how, in the above experiments, 'attentive' behaviour was assessed, though in the studies of the visual system the cat's 'attention' was attracted, among other things, by a call or by fish odour delivered to the cage When a cat is called, it may look toward the source of the voice when a fish odour is blown into the cage the cat usually responds by sniffing and looking toward the source of the odour If the animal failed to make these responses, it is not apparent how 'attentive' behaviour was otherwise assessed Hence it is difficult to escape the conclusion that presentation of a non-visual stimulus may have resulted in the cat searching the visual field The above experiments do not therefore exclude the possibility that the evoked responses were reduced in the modality actually being used for examining the sensory field

The following experiments were undertaken to determine the changes in cortical evoked response to light flash in the unanæsthetized cat, when its behaviour was directed toward an object in the visual field (mouse) and to a non-visual stimulus (conditioned tone) respectively Six cats were used A monopolar electrode of approximately 1 mm tip diameter was placed on the visual cortex using as indifferent electrode a screw driven into the frontal bone Several days after operation the animal was put in a box illuminated by a 6-volt battery bulb

Evoked responses to flash were displayed on an oscilloscope and filmed while the cat was resting facing the stroboscope. The flash, delivered once in approximately 2 sec., was of 1-m. sec. duration with an intensity of approximately 1 lambert. A mouse was introduced between stroboscope and cat, separated from the latter by a transparent plastic sheet. During the first few presentations of the mouse, the cat usually was intensely excited; but later it sat still, intently watching the mouse with little or no pilo-erection, or unsheathing of the claws. At this time 20 evoked responses to flash were recorded. Ten of these experimental responses were selected at random from the 20, together with 10 control evoked responses from the resting animal, recorded immediately before introduction of the mouse. The mean of each of these sets of results was calculated. These means for each animal were tabulated and the significance of any differences between experimental and control conditions obtained by applying a paired *t* test. It was found that when the cat was watching the mouse the electrocorticograph was flattened. The surface positive component of the primary wave of the evoked potential was decreased by 27 per cent ($P < 0.001$), and its duration reduced by 20 per cent ($P < 0.01$). The amplitude of the surface negative component was decreased by 21 per cent ($P < 0.02$). The excursion of the second wave of the response was reduced by 19 per cent ($P < 0.02$) and waves of the later components by 51 per cent ($P < 0.001$).

In order to orientate the cat's behaviour to a non-visual modality, the animal was conditioned to receive a slight shock to the fore-limbs after several tones, each delivered in the interval between consecutive flashes. The number of tones delivered prior to the shock was varied between 2 and 10 in any trial. After the first few trials, shocks were only occasionally applied. During the early stages of conditioning, at the onset of the tones, the cat looked intently around the box. At this time the electrocorticograph was reduced in amplitude. The surface positive component of the primary wave was reduced by 21 per cent ($P < 0.02$) and its duration by 19 per cent ($P < 0.02$); the amplitude of the second wave of the response was attenuated by 34 per cent ($P < 0.01$) and the later oscillations by 40 per cent ($P < 0.02$).

At a later stage of conditioning, the cat did not look around the box during the tones, but remained still except for some slight shifting of the fore-limbs, twitching of the facial muscles and flicking of the ears. Occasionally at this stage the cat got up during the tones and settled in another part of the cage. Measurement of records taken when the animal showed minimal movement and when its response to the acoustic stimulus was accompanied by little or no 'visual searching' component showed that the amplitude of the electrocorticograph was diminished. The amplitude and duration of the evoked responses were not, however, significantly different from those recorded under control conditions.

From the above results it appears that photically evoked responses in the visual cortex are not attenuated when a cat's behaviour is orientated to an acoustic stimulus, so long as there is no visual searching component in the animal's behavioural response. On the other hand, when the animal's behaviour is directed to a stimulus in the visual field, or shows some visual searching component in its response to a non-visual stimulus, evoked potentials are reduced in amplitude. It might be argued that when the cat was looking at a mouse the information contained in the flash was irrelevant and so attenuated. However, when the animal's behaviour was directed to the acoustic stimulus, in the absence of visual searching activity, the information from the flash was likewise irrelevant. The evoked potentials in these two situations should therefore have been treated similarly. They were not.

Reduction in amplitude of an evoked response to a given photic input may be brought about in one or more ways (for example, inhibition, reduction of facilitation, occlusion). Whatever the mechanism, one of the effects of such activity may be, in some circumstances, to increase sensory contrast and so improve the sharpness of input boundaries. Absence of such input attenuating activity in the visual system, as when behaviour is directed to an acoustic stimulus, could give a greater absolute sensitivity in the visual pathway. The animal would thus monitor its environment more sensitively so providing central mechanisms with a maximum of information on which to act.

One of us (G. H.) wishes to thank the Wellcome Trust and the National Research Council of Canada for grants toward the cost of travel expenses. Thanks are also due to Prof. H. Jasper for his interest in this work.

INFLUENCE OF UNBALANCED GROWTH ON SUBSEQUENT X-RAY-INDUCED INHIBITION OF DEOXYRIBONUCLEIC ACID SYNTHESIS IN *ESCHERICHIA COLI* 15_{T-}

By DANIEL BILLEN

Department of Biology, Section of Microbiology, University of Texas, M. D. Anderson Hospital and Tumor Institute, Houston, Texas

IN an earlier report[1] it was demonstrated that the number of survivors among X-irradiated *Escherichia coli* strains *B/r* and 15_{T-} (thymine-less) was increased when log-phase cells were incubated in the presence of chloramphenicol prior to X-ray exposure. In the case of *E. coli* 15_{T-} deoxyribonucleic acid synthesis was necessary for the development of radioresistant cells, since when deoxyribonucleic acid synthesis was prevented by the removal of thymine from the pre-irradiation incubation medium, radioresistance was not enhanced by chloramphenicol. One interpretation of these results was that 'surplus' deoxyribonucleic acid formed in the presence of chloramphenicol (higher ratio of deoxyribonucleic acid/protein than in non-treated cells) was biologically active and increased the number of sensitive sites in the bacterium[1] An additional possibility considered was that pretreated cells, unbalanced in macromolecular constituents, were in special physiological states such that the probability of overcoming X-ray induced lesions was increased Using cells in the several unbalanced states with regard to protein, deoxyribonucleic acid, and ribonucleic acid levels we have studied deoxyribonucleic acid synthesis after X-ray exposure of such cells In the present work results are presented which show (1) An inhibition by chloramphenicol of phasing or 'synchronization' of the deoxyribonucleic acid-synthesizing system and (2) that the radiosensitivity of the synthesizing mechanism is altered by previous chloramphenicol exposure

The conditions for obtaining log phase as well as establishing 'unbalanced phase' growth were those previously described[1] Following the various treatments to be described for obtaining unbalanced growth, the cells were cooled in an ice-bath, harvested, washed and resuspended in cold minimal-salts–glucose medium to give a final concentration of about 20 times the original number (1–2 × 10^{10} cells/ml) in order to obtain satisfactory levels of material for chemical analysis The concentration of cells during exposure was higher than the level used in the earlier studies by a factor of approximately 100 , as a result the number of colony-formers found after a dose of 10,000 r was higher in the experiments reported here[2,3] Following X-ray exposure at ice-bath temperature the cells were added to twice the original culture volume of pre-warmed minimal medium supplemented with 20 μgm /ml thymine and re-incubated with aeration at 37° C Aliquots of this culture were removed at intervals for analysis as detailed earlier[1]

Prior to treatment with 10,000 r of X-rays, log phase *E coli* $15T_{-}$ cells were incubated in minimal medium at 37° C for 1 hr under the following conditions (*A*) incubation in the presence of thymine (normal log-phase cells), (*B*) incubation in the presence of 10 μgm /ml chloramphenicol and (1) plus thymine (increased ribonucleic and deoxyribonucleic acid/protein content), or (2) without thymine (increased ribonucleic acid/deoxyribonucleic acid and protein content) , (*C*) incubation in the absence of thymine (increased ribonucleic acid and protein/deoxyribonucleic acid content)

In normal log-phase *E coli* $15T_{-}$ (condition *A*) exposed to 10,000 r of X-rays, deoxyribonucleic acid synthesis proceeded rapidly for 30–60 min (Fig 1) This was followed by a period in which no net synthesis was detectable In other experiments in which survival was higher than that found in the experiment from which the data of Fig 1 were taken, renewed synthesis was sometimes seen by 90 min The number of colony-forming cells in the irradiated suspensions (10–25 per cent of the controls) remained constant or showed a slight decline during the first 30 min A rapid increase then occurred that probably accounted for the renewed synthesis observed in some experiments

When chloramphenicol was added to log-phase cells (condition *B*1) ribonucleic and deoxyribonucleic acids continued to accumulate while protein synthesis was largely inhibited[1] Such cells washed free of the antibiotic and re-incubated in a thymine-supplemented minimal medium showed a delay of approximately 30 min before net deoxyribonucleic acid synthesis was resumed (Fig 1) When the washed cells treated with chloramphenicol were exposed to 10,000 r of X-rays and then resuspended in thymine-supplemented medium no net increase in deoxyribonucleic acid content was observed during the 2 hr the cultures were studied (only the first 90 min are shown in Fig 1) A similar result was found for cells washed free of thymine prior to incubation in thymine-free minimal medium to which chloramphenicol has been added (condition *B*2) During such incubation only ribonucleic acid was observed to accumulate in large amounts during the 1 hr exposure to the antibiotic[1] As seen in Fig 2, deoxyribonucleic acid synthesis in such cells was completely suppressed after X-ray exposure

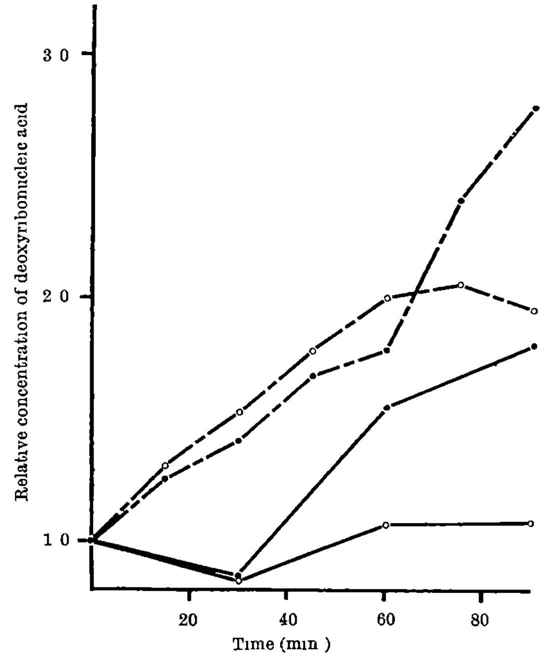

Fig 1 The influence of prior chloramphenicol treatment on subsequent deoxyribonucleic acid synthesis Prior to treatment with 10,000 r of X-rays, log-phase *E coli* $15T_{-}$ cells were incubated for 1 hr under the following conditions ●- - -●, normal log-phase cells (condition *A* of text) , ○- - -○, condition *A*, and then exposure to 10,000 r , ●——●, exposed to chloramphenicol (condition *B*1) , ○——○, condition *B*1, then exposure to 10,000 r

Log-phase cells, washed free of thymine and then re-incubated for 1 hr at 37° C in thymine-free minimal medium (condition *C*), showed a marked increase in ribonucleic acid and protein nitrogen while deoxyribonucleic acid synthesis was essentially nil[1] This was the 'unbalanced growth' reported for this strain of *E coli* by Barner and Cohen[4] Following this treatment the cells, after harvesting and washing at ice-bath temperatures, appeared to be synchronized[5] with respect to deoxyribonucleic acid synthesis (Fig 2) The deoxyribonucleic acid nearly doubled in 30 min This was followed by a period of reduced deoxyribonucleic acid synthesis before a new rate of deoxyribonucleic acid accumulation was seen X-irradiation did not greatly alter the synthesis during the initial doubling period (Fig 2) However, after this initial burst no further increment was found during 120 min of observation The loss of acid-insoluble deoxyribonucleic acid observed in the irradiated cell culture after 60 min was due to lysis of a portion of the cells as reflected by a decreased turbidity of the cultures as well as a reduction in the harvested cell yield (protein) The surviving cells did not grow at a sufficiently

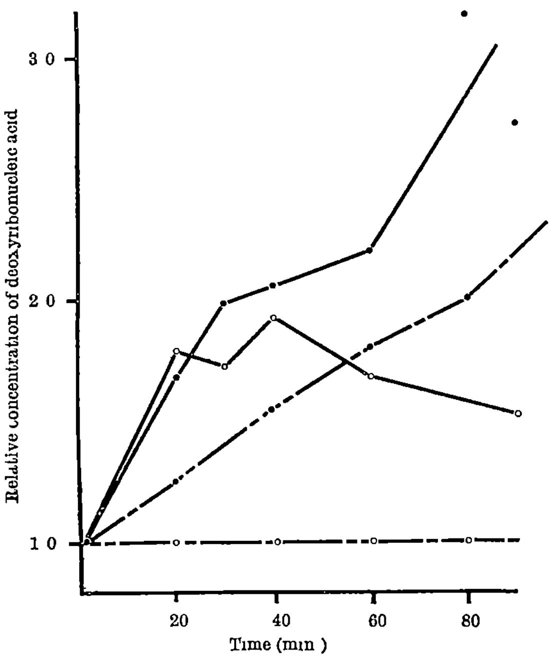

Fig 2 The effect of thymine starvation during chloramphenicol exposure on subsequent deoxyribonucleic acid synthesis Prior to treatment with 10,000 r of X-rays, log-phase *E coli* $15T_-$ cells were incubated for 1 hr under the following conditions ●——●, incubation in the absence of thymine (condition *C* of text), ○——○, condition *C*, and then exposure to 10,000 r ●---●, exposed to chloramphenicol in the absence of thymine (condition *B*2), ○---○, condition *B*2, and then exposure to 10,000 r

rapid rate to be reflected in the analysis during these 2 hr It required more than 2 hr for dividing survivors to reach the initial level of unirradiated cells of the controls

Thus, during the incubation in the absence of thymine (condition *C*), a radioresistant synchronization of deoxyribonucleic acid appeared to have occurred Similar treatment did not synchronize ribonucleic acid or protein synthesis[6] The addition of chloramphenicol to such cells prevented the development of the radioresistant system synthesizing deoxyribonucleic acid It is also apparent that the addition of chloramphenicol to log-phase *E coli* $15T_-$ incubated in the presence of thymine resulted in a physiological state such that deoxyribonucleic acid synthesis did not occur immediately after removal of the antibiotic Cells in this physiological state could not synthesize deoxyribonucleic acid until a radiosensitive process had been initiated Although the mechanism whereby chloramphenicol brings about this effect is unknown, it is tempting to speculate that the antibiotic-induced inhibition of protein synthesis was involved The protein (and/or ribonucleic acid) synthesized in a given time period (in the presence or absence of net deoxyribonucleic synthesis) may be a necessary prerequisite for subsequent deoxyribonucleic acid synthesis One may envisage this protein as being involved in the formation of a template[7–10] or as specific enzymes perhaps similar to the polymerases described by Kornberg and collaborators[11] which were found to be capable of *in vitro* deoxyribonucleic acid synthesis Additional experiments planned may provide further insight into the true nature of the radiosensitive process inhibited by chloramphenicol

The results with irradiated *E coli* $15T_-$ correlate well with the findings of others in plant[12] and animal[13,14] studies that there is a radiosensitive process involved in deoxyribonucleic acid synthesis which is not the deoxyribonucleic acid replication system itself The radiosensitive process occurring prior to actual deoxyribonucleic acid synthesis may involve protein synthesis as suggested from the results presented here Log- or stationary-phase cell suspensions when exposed to X-rays contain organisms in various phases of their division cycle One may speculate that there occurs, in normal growth of individual cells, a phase such that the products of the radiosensitive process are exhausted and must be synthesized anew before deoxyribonucleic acid replication can proceed If most cells of an exposed population were in the active deoxyribonucleic acid synthesizing (radioresistant) phase they would continue to make deoxyribonucleic acid until a predetermined level would have been reached Therefore at doses of X-rays in which most of the population no longer were colony-forming cells a good amount of deoxyribonucleic acid as well as ribonucleic acid and protein synthesis would occur[6] The extent of deoxyribonucleic synthesis would be determined by the length of the deoxyribonucleic synthetic period relative to that of the sensitive pre-synthetic phase In a log-phase population most cells would be in the deoxyribonucleic acid synthesizing phase if this period occupied most of the division cycle of the cell Based on this model our results would suggest that most log-phase cells are not in the radiosensitive period since irradiated populations increased significantly their deoxyribonucleic acid-levels upon reincubation The radiosensitive pre-synthetic process, having been inhibited by radiation exposure, would no longer function and thus deoxyribonucleic acid synthesis would come to a close if it is assumed that the radiosensitive process is permanently inhibited by irradiation When sufficient numbers of survivors were present these would grow at a rate reflecting their physiological state prior to exposure and eventually produce measurable amounts of deoxyribonucleic acid If the number of survivors were high enough and exhibited little lag upon resuspension in a complete growth medium they would produce sufficient amounts of deoxyribonucleic acid to be measurable soon after exhaustion of deoxyribonucleic acid synthesis in dying cells Thus the termination of deoxyribonucleic acid synthesis in dying or dead cells would be masked by the dividing viable cells At higher doses of X-irradiation deoxyribonucleic acid synthesis may be completely suppressed by the destruction of the radioresistant deoxyribonucleic acid synthesizing mechanism itself[6]

APPOINTMENTS VACANT

APPLICATIONS are invited for the following appointments on or before the dates mentioned

ASSISTANT LECTURER IN CHEMISTRY at the University of Canterbury, Christchurch, New Zealand—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W C 1 (September 30)

ASSISTANT LECTURER (with an honours degree in geology and with ability to lecture in historical geology and micro-palæontology) in GEOLOGY at the University of Canterbury, Christchurch, New Zealand—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W C 1 (September 30)

ASSISTANT LECTURER IN SOCIAL ADMINISTRATION—The Registrar, The University, Manchester 13 (September 30)

ASSISTANT LECTURERS IN BOTANY—The Registrar, The University, Manchester 13 (September 30)

CHAIR OF EDUCATION in the University of the Witwatersrand, Johannesburg, South Africa—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W C 1 (September 30)

SENIOR LECTURER IN THE DEPARTMENT OF GEOPHYSICS at the University of the Witwatersrand, Johannesburg, South Africa—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W C 1 (September 30)

SENIOR LECTURER or LECTURER (with an honours degree in engineering and preferably with some professional experience since graduation) IN MECHANICAL ENGINEERING—The Registrar, King's College, Newcastle upon Tyne (September 30)

READER or SENIOR LECTURER (wtih experience in experimental physics, experience in some aspects of applied physics would be of particular value) IN THE DEPARTMENT OF PHYSICS, to help arrange, and to take part in, the teaching of physics to engineers at all levels—The Registrar, The University, Manchester 13 (October 5)

DIRECTOR (with a wide scientific background) OF THE COMPUTATION CENTRE—The Vice-Principal, McGill University, Montreal, Que , Canada

LECTURER (with a good honours degree and some practical experience, preferably in the field of structural steelwork , some teaching experience would be an advantage) IN THE DEPARTMENT OF CIVIL ENGINEERING—The Registrar, The University, Bristol

LECTURER (with an honours degree in chemistry and postgraduate experience of academic or industrial research) IN INORGANIC CHEMISTRY—The Secretary, Sir John Cass College, Jewry Street, London, E C 3

RESEARCH ASSOCIATIONS AND THEIR FUNCTIONS

IN its report for the year 1958, the Council for Scientific and Industrial Research discussed briefly its general policy towards the research associations, expenditure on which, in revenue and capital grants, it envisaged as rising by about a third during the next five years, because their scope and activities are growing steadily in response to the expressed needs of industry The Council's policy, however, is that industry should bear an increasing share of the total operating cost of the associations, and it is envisaged that over the next five years grant-earning income from industry will be 46 per cent greater than during the past five years, while the grants themselves will be only 34 per cent greater For the year ended March 31, 1958, annual grants to the associations totalled £1,700,330, compared with £1,424,830 in the previous year, with special grants of £32,571, compared with £126,954 The total income of the associations is given as just under £7 million It was stated that during the fifteen months ended December 31, 1958, new or revised terms of grant had been awarded to ten of these associations

The new terms are set out in "Research for Industry, 1958"* (see also p 238 of this issue) This report on the work of the industrial research associations includes a summary of the report of the Industrial Grants Committee, which at the request of the Council has surveyed the work done by research associations, and the methods used to assess the applications for grants received from industry The main conclusions and recommendations of this Committee have been accepted by the Council and, besides considering research association grant policy in the period 1957–64, the Committee's report reviews particularly the achievements of the ten associations which have received new or modified terms of grant "Research for Industry, 1958" also includes an assessment by Dr D T A Townend of the place of the research associations in the evolution of scientific endeavour in Great Britain, and a report prepared for the Committee of Directors of the Textile Research Associations on how co-operative research serves the textile industries These two surveys throw rather more light than the new terms of grant on how in practice the Council's new policy is being interpreted

The Industrial Grants Committee was greatly impressed with the rapid progress of research associations towards maturity and with the rising quality of the research they carry out and the services they give to industry The Council is satisfied that co-operative research, as fostered by the Department, is of great value to industry and the nation, and that the Department of Scientific and Industrial Research should continue to give it whole-hearted support All told, the grant-aided organizations in the scheme serve about 55 per cent of British manufacturing industry, and besides basic and applied research their activities include the study of factory operations and working conditions, library and information services and technical and advisory work for individual firms The largest single function is applied research on problems common to the whole of the industry served

The Council also endorses the Committee's view that co-operative research brings important specific benefits to industry, economizing on money and scientific man-power, and offering a scientific service to firms that cannot afford research departments of their own It helps to guide industry towards an appreciation of the value of research in general and facilitates an exchange of technical information and other forms of mutual assistance Finally, it builds up a store of knowledge on which the nation, through Government departments, can draw

These are large claims, some of which have been challenged, at least to the extent of asking whether certain functions could be more efficiently served in other ways or by changing the technical character of the associations themselves Nevertheless, their acceptance by the Council seems to dispose of any suggestion that the Council is intending to wind up some of the research associations Indeed, it is specifically stated that the expansion contemplated over the next quinquennium allows for an increase in their number, since recent estimates of the Department suggest that nearly a fifth of the net output of British manufacturing industry comes from trades which in the Committee's view are not fully covered by existing research facilities Some of these trades might in future be appropriately served by grant-aided research associations

Until the Second World War, Government aid to research associations in Britain was based on the assumption that they would eventually support themselves entirely In 1945, however, it was decided that this policy was no longer in the national interest, and that industrial grants should become one of the continuing activities of the Department The procedure now generally followed is to award a basic 'block' grant and supplement it with an 'incentive' payment which varies (up to a maximum) according to what income an association can raise from its members Aid is generous to a young research association serving an industry which does not yet recognize the full value of research, but, as the association establishes itself and increases both the scale of its work and the contribution science can make to the productivity of its member firms, the incentive is gradually reduced, and it ceases altogether when the association reaches its appropriate size

Even so, Dr D T A. Townend points out that eleven associations have an annual income of less than £50,000 and only two receive more than £500,000 Eighteen have incomes between £50,000 and £100,000, eight between £100,000 and £250,000, and seven between £250,000 and £500,000 These are not high figures for research to-day, and it could be asked whether they are always high enough for efficiency The Industrial Grants Committee is clearly asking the right questions when a grant comes up for review at the end of five years, and the Council accepts its view that it is important to continue paying a block grant after the association has reached an appropriate size

---

* Department of Scientific and Industrial Research Research for Industry 1958 a Report on Work done by the Industrial Research Associations in the Government Scheme Pp iv+135 (London H M Stationery Office, 1959) 7*s* 6*d* net

This size obviously must take account of the adequacy of the facilities of an association for effective research, but the Council concurs in the Committee's view that continuance of the block grant will enable the Department to exercise an important and beneficial influence on industrial research and ensure that each association has the necessary proportion of basic research in its programme It is also argued that a channel is thus kept open for the steady flow of research results to Government departments , this helps to prevent undesirable overlapping of projects and to secure desirable co-operation on programmes of wide interest

Before these propositions are accepted, their implications for the Council of Scientific and Industrial Research require examination They presuppose the existence of an administrative structure for which even the Lord President of the Council has disclaimed responsibility Some overlapping should certainly be prevented by the Council for Scientific and Industrial Research , but it should be clear from the discussion aroused by recent proposals for a programme of space research to be undertaken by Britain that there is by no means general agreement that administrative arrangements are yet such as to ensure the minimum of overlapping, much less the most desirable balance and distribution of research effort

Since the policy of reducing incentive grants was adopted in 1951, the overall ratio of grant to industrial income has fallen from 1 · 1 65 to 1 2 5, and the lowest individual ratio is now 1 4 6 There is nothing mechanical about the trend, and although the ratio is not given for the ten associations for which the terms of grant were revised during the past year, the ratio of incentive grant to additional income varies from 1 1 to 1 2, and the maximum incentive grant from £3,000 to £18,000 These figures show, however, that the reduction of incentive grants is being exercised with the flexibility which the Council adumbrates

It is recognized that a long time may be required for an association to convince industry of the value of its work and that if the incentive grant is reduced too quickly, industrial research may be discouraged and the purpose of the grant defeated Likewise, changes in the purchasing power of money have to be considered, particularly when research associations receive only a block grant An allowance to restore the real value of the grants was made in 1955, and the Industrial Grants Committee recommends a similar provision if necessary for the next quinquennium

More important than this question of finance, however, is that of function The Council endorses the Industrial Grants Committee's view that it is very important to keep a proper balance in the activities of the associations between basic research, applied research (including development work) and information, liaison and consultant services In some industries pioneering studies of factory operations and working conditions are best made on a co-operative basis, and the Council believes that research associations should extend this work where conditions are suitable, and that, wherever appropriate, the Department of Scientific and Industrial Research should carry out its research in this field and disseminate the results, in close collaboration with the associations

No indication is given as to what is regarded as a proper balance between the various activities That will naturally vary from industry to industry, as well as with the maturity of the association It is left for Dr Townend to supply a rough estimate as to the proportion of the £7 million of the total income which is spent on fundamental research, though this estimate does not necessarily also indicate the proportion of man-power which is devoted to fundamental research Of a total staff of some 5,000, 1,450 are graduates or possess equivalent qualifications, 1,750 are research assistants, 850 artisans and 950 administrative staff

Both the Council and its Industrial Grants Committee hold that, so long as co-operative research programmes do not suffer, research associations should be encouraged to undertake a reasonable amount of sponsored research Some associations are already prepared to do so, and generally have a small proportion of their staff engaged in this way The practice offers definite advantages in giving research workers useful experience and in strengthening the contact between research associations and industry

The Council insists, nevertheless, that the chief task of the research associations is co-operative research and that there are other facilities for sponsored research, offered by private bodies without Government assistance It would welcome increased participation by research associations in sponsored research, but such activities must be kept within reasonable limits In future a grant-aided association is free to undertake sponsored projects without consulting the Industrial Grants Committee provided the income arising is unlikely to exceed 15 per cent of total income in any year, and that the estimated cost of any one project is not more than £5,000

Dr D T A Townend's review examines this question of function a little further He points out that the present total income of the research associations in Britain, namely, £7 million, must be compared with the expenditure of private industry on research and development of £58,000,000, or 0 8 per cent of industrial output , and this £7 million is less than half the £14 4 million expended on research undertaken within the universities in science, technology, medicine and agriculture, towards which the Government provided about £12 million The universities are mainly concerned with extending the frontiers of scientific knowledge in an atmosphere of intellectual freedom and usually without regard to the immediate and specific applications of their work Industrial laboratories, he suggests, are mostly devoted to study of the processes and products of a particular firm, with the object of developing something which that firm can do, and will do, probably to the exclusion of others

That the last proposition should not be accepted without qualification does not, however, affect the validity of Dr Townend's claim that the research associations are in a unique position to pinpoint the research problems of importance to the whole of their respective industries The validity of that claim depends rather on the effectiveness of their contact with the industries they serve, their ability to recruit and retain staff of appropriate experience and ability, and on the quality of their directorate Some of these factors can be influenced by the Council for Scientific and Industrial Research, but only to a limited extent, and they should be borne in mind in considering Dr Townend's argument There is a separate domain between the universities and industry, he argues, in which knowledge of the basic principles of industrial processes has to be sought with a particular and definite objective This region accordingly is mostly unsuitable for the universities and is also somewhat too long in range or too expensive, at least for the smaller industrial firms in their own laboratories This, he claims, is particularly the domain of the research associations, with their resources and teams of scientists capable of covering a variety of disciplines with a character and individuality of their own There is no fuss about claiming freedom of action—the Industrial Grants Committee is emphatic as to the need for preserving the autonomy of the associations—nor are unattractive features of the field of investigation neglected

Dr Townend believes that industry in Britain has been well served by the research associations for many years in a well-defined field uniquely appropriate to the associations, with no fear of overlap, and he also suggests that the practice in most associations of pursuing both long-range and short-range objectives side by side contributes to the long-term future of the industries they serve, as well as to the virility of the overall activity of the associations As to the balance of research, Dr Townend refers to a recent survey of the activities of some thirty-two associations, which showed that the proportion of effort devoted to basic research varied from 10 per cent to 67 per cent, the average being about 28 per cent, whereas that devoted to applied research averaged 63 per cent Close contact has almost invariably been established between the associations and the universities, wherever research work of relevance to that of the association is already undertaken at universities Sometimes the associations assist university departments by contracts or by financing fellowships or bursaries, and this assistance may be given to an existing programme in a university department, or an association may seek to arouse the interest of a university department in a new subject Dr Townend appears to be satisfied that these arrangements are adequate They increase the 'thinking potential' of an association and help to relate the work of university scientists to the needs of industry Often they are particularly effective in ensuring that university workers are provided with a correct translation of an industrial problem into scientific terms, and they supplement the necessarily limited results obtained by postgraduate students with ancillary measurements and background information, thus enabling the results of the work to be applied more readily What is not specifically stressed is the atmosphere for research which the associations could provide and which was rightly stressed by Mr J Wilson in his Hinchley Memorial Lecture last year, and this atmosphere is one which the Council for Scientific and Industrial Research could certainly foster

Clearly the interchange of staff between the research associations and the universities can be beneficial here, but Dr Townend notes that such transfer has decreased in recent years, possibly in consequence of the general shortage of scientists and of the rapid growth of departments of science and technology within the universities This interchange could well be as important as the interchange of staff between the associations and industry itself, and valuable as may be the contributions of the associations in research, they will only render their full service to industry when such interchange of staff proceeds freely and to the maximum extent It can be an important factor, as Dr Townend notes, in supplying industry with senior staff at the managerial as well as the technical level, and the educational potential of the associations is not the least reason for justifying the continuance of support from the Department of Scientific and Industrial Research There may well be scope for further specific development of the training potential of the associations without interfering with their primary and main function of co-operative research It should be clear, however that if they are to render their full contribution to industrial development, they must be assured not only of wise and far-sighted leadership, but also of sustained financial support, probably on a more generous scale than the resources at present available to the Department of Scientific and Industrial Research have yet permitted.

ROCKETS AND SATELLITES

Manual on Rockets and Satellites

Edited by L V Berkner, in association with Gilman Reid, John Hanessian, Jr, and Leonard Cormier. (Annals of the International Geophysical Year, Vol 6) Pp xx+508 (London and New York: Pergamon Press, 1958) 160*s*

THERE is little doubt that this volume of the Annals of the International Geophysical Year contains the most comprehensive account yet published of the researches being carried out and the methods and techniques being used in the fields of rockets and satellites Any book dealing with such a young and rapidly growing subject will inevitably date rather quickly, and it so happened that the launching of the first Russian Earth satellite occurred at a very late stage in the preparation of this work. The preliminary account of the Russian results, and the rapid switch in the emphasis of the American satellite programme from the *Vanguard* to the *Explorer* series, are dealt with rather briefly in annexes. It is perhaps fortunate that we have on record here, written before it was overtaken by events, the American plan for the scientific programme intended for the *Vanguard* satellites.

Viewed as a whole the volume cannot fail to be an invaluable source of reference to workers in the field. The upper atmosphere research rocket which still has a vital part to play is not neglected, but the greater part of the book is devoted to Earth-satellite programmes and plans. Those whose interest is more general will gain an insight into the complexities of planning and the widespread co-operation needed in a space research programme, in addition to a sober review of the many new avenues of scientific research now being opened. The volume takes the form of a series of scientific papers, covering subjects as diverse as the design of instruments for many rocket- and satellite-borne experiments, and the organization of volunteer visual observing teams, both in the United States and in the U.S.S.R. It is indeed pleasing to find an international flavour throughout, with significant contributions from the U.S.S.R.

The book is handsomely produced and illustrated, as is to be expected for the price. One must hope that the end of the International Geophysical Year itself will not prevent the compilation of further authoritative international volumes in these expanding fields.

MICROCOSM TO MACROCOSM

Matter, Earth and Sky

By Prof. George Gamow. Pp. xi+593. (London: Macmillan and Co., Ltd., 1959.) 50*s*. net.

EXUBERANT and encyclopædic are the only terms to describe this interpretation of the material universe, most appropriately dedicated to "Aspiring Youth". In the days of stone-turning and avenue-exploring, barriers had to be either surmounted or torn down; Prof. Gamow himself was the first to realize that with the right kind of approach nothing so drastic is needed, and that they can be gently tunnelled through. There is certainly a barrier between the experience of the ordinary individual and the physicist's interpretation of it. In this book, without demanding excessive penetration on the part of the reader, the author has successfully brought into the open the truths that occupy the inner levels of the well.

The style follows the author's usual successful formula—saying what comes naturally. There are some old friends, including C. G. H. Tompkins, translated to an American setting, but still on a communal Cambridge bicycle. The illustrations are excellent, original and relevant—even those that are put in just for fun, like the one showing an 'experiment' on the thermal expansion of a body, which looks rather unkind. Scientists are pictured with a richly human touch—Otto Hahn registering sheer amazement at the fission of uranium, Compton strumming his banjo with effect, and Bohr in orbit on a motor-cycle.

The book is divided into three sections. The first, on "Matter and Energy", deals with the elementary physics of the surroundings, relating everyday observations to fundamental principles. This ranges widely from simple mechanics to computers and satellites and rocketry and relativity. The second, entitled "Microcosm", starts with the kinetic view of matter in terms of molecules, and covers atomic and nuclear physics, and a good deal besides. The chapter on the chemistry of life, which goes very fully into protein structure, and discusses Watson and Crick's model of the structure of deoxyribonucleic acid and its implications for the possible working of heredity, is important both for its contents and its influence on the young reader who may (though not if he has got so far through the book) tend to regard physics as a little remote from living. The third part, "Macrocosm", deals with the Earth and its history, the planets, the evolution of the stars, the origin of the elements and of the galaxies, and the recent theory of continuous creation.

So much could not have been achieved in a single book without very careful planning of the sequence of material, and much skill has been devoted to placing the discussion of a fundamental topic in relation to the general framework. Electrolysis, for example, appears in the second part, where the electrical nature of matter is treated. This means that it is a book to be read through, without dodging back to the beginning for explanations.

It is a splendid book, and highly to be recommended to the general reader and for the library. Although very good value for money, its price unfortunately places it high up in the gift-book class. The unkind experiment mentioned above supposes the co-operation of a good-natured relative, and any aspiring youth who can get such a one in an expansive mood would be well advised to clamour for this book as a present instead.
G. R. NOAKES

SURVEYS IN 'APPLIED' MATHEMATICS

Some Aspects of Analysis and Probability

By Irving Kaplansky, Marshall Hall, Jr., Edwin Hewitt and Robert Fortet. (Surveys in Applied Mathematics, Vol. 4.) Pp. xi+243. (New York: John Wiley and Sons, Inc.; London: Chapman and Hall, Ltd., 1958.) 72*s*. net.

THIS book is the fourth of John Wiley's "Surveys in Applied Mathematics"; its production was sponsored by the United States Office of Naval Research and by the editorial board of "Applied Mechanics Reviews"; its authors are described as being, and indeed are, "internationally recognized authorities in the areas of applied mathematics covered by their surveys". Hall writes on combinatorial analysis, and Fortet on probability theory, while functional analysis and abstract harmonic analysis are surveyed respectively by Kaplansky and Hewitt. An English reader, accustomed to the rigid division between applied mathematics (where nothing is proved) and pure mathematics (where nothing is useful) may well find the classification puzzling. Only the probabilist will be untroubled by it; his subject, having an axiomatic foundation and yet deriving all its inspiration from practical problems, has no place in the traditional classification , he will be quite happy in the applied mathematical club so long as the topological-algebraists are there to keep him company

Kaplansky's article (32 pages) is the shortest in the book, but is supported by a magnificent bibliography of 113 entries, nearly half of them concerning papers by Russian authors , he gives a remarkably clear and concise account of many topics of current interest in the theories of Banach spaces, locally convex spaces and Banach algebras

Hall's survey of combinatorial analysis will be of value not only to algebraists but also to statisticians interested in the existence and construction of designs and to the industrial mathematician concerned with linear programming For the latter there is a fascinating chapter on the theorems of Philip Hall, Konig and Ramsey, and their applications , these include the transportation problem, the travelling-salesman problem, and also such curiosities as the following (Erdős and Szekeres, 1935) "There exists an integer-valued function $N(n)$ of the integer variable n such that every set of N points in the plane, no three on a line, will contain n points forming a convex n-gon"

Hewitt's long article on abstract harmonic analysis presents a connected account of a difficult and important field, which is the more valuable because a large number of the most important papers reviewed here were published in Russian Readers of the older text-books on Lebesgue integration encounter theorems of two kinds those which make essential use of the group structure of the real line, and those which do not Those which do not (for example, the Lebesgue convergence theorems) properly belong to measure theory, while those which do (for example, theorems about convolutions, and the whole of the Fourier theory) can nearly all be generalized to the situation in which the real line is replaced by a (say, abelian) locally compact group and Lebesgue measure is replaced by Haar measure, and this is the situation with which abstract harmonic analysis is concerned

Fortet gives a most valuable account of a number of special topics in probability theory, of which the most characteristic is development of techniques for handling random elements of general type A probability space is a non-vacuous set Ω, a Borel field $\mathcal{F}$ of 'measurable' subsets of Ω, and a totally finite measure μ on $\mathcal{F}$ normalized so that $\mu(\Omega) = 1$ A random variable $x(\ )$ is a mapping from Ω to the real line such that all counter-images of real intervals are $\mathcal{F}$-measurable, and an n-dimensional random variable is defined similarly The classical theory was concerned exclusively with finite sets of such random variables , the modern theory of stochastic processes is concerned with infinite sets of random variables, suitably parametrized, and the theory of general random elements is concerned with (in the first instance single) random variables $x(\ )$ where now the range of the mapping $\omega \rightarrow x(\omega)$ lies not on the real line nor in n-dimensional euclidean space, but in some more general topological-algebraic structure For example, Mourier and Fortet have studied random variables taking values in a Banach space, and Gel'fand has studied random (Schwartz) distributions In a sense the distinction between stochastic processes and general random elements is artificial, for if $\omega \rightarrow x(t,\omega)$ (for each t in some parameter set T) is a set of random variables constituting a stochastic process, then $\omega \rightarrow x(\ ,\omega)$ can be thought of as a general random element, and conversely most of the general random elements one wishes to consider in practice (random age-distributions, random energy-spectra, etc) can be reduced to systems of numerical random variables But the direct treatment of a random variable of general type, where possible, offers many attractions, and there can be no doubt that this branch of the subject will attract considerable attention during the next few years

The publishers are to be congratulated both on the quality of the surveys included in this volume and on their decision to publish this group of four surveys together D G KENDALL

FUTURE MARINE BIOLOGICAL RESEARCH

Perspectives in Marine Biology

A Symposium held at Scripps Institution of Oceanography, University of California, March 24–April 2, 1956 Edited by A A Buzzati-Traverso Pv xvi + 621 (Berkeley and Los Angeles University of California Press , London Cambridge University Press, 1958) 75*s* net

"APPROXIMATELY 90 to 95 per cent of all biologists are engaged in terrestrial biology. . These biologists have a tendency to consider Marine Biology as a somewhat secondary biological annex " P Drach (p 603 *et seq*) further states that general biology can never be properly balanced if based predominantly on terrestrial forms, however important they are to our welfare, a view shared by many of the contributors The expansion of marine biology is reflected by the wide range of subjects presented at a symposium planned to focus attention on forthcoming fields of marine research It is significant that a number of contributions come from non-marine biologists Forty-one papers, with subsequent discussions, are arranged in four sections : ecology , physiology and biochemistry , behaviour , evolution and genetics

Ecological papers by P Drach, L Zenkovitch, G Thorsen, A C Hardy and others, while emphasizing that more field observations on animal communities are required, show the urgent need for new design and international standardization of instruments and techniques for quantitative sampling Field observation is so much stressed that K M Rae's plea, echoed elsewhere, for laboratory observation and experiment on marine equivalents to the guinea pig and fruit fly stands out from the rest D P Wilson's studies on the ability of organisms to detect factors at present defying analysis, and so select a particular substrate, are stimulating Further emphasis on this need for study on microconstituents is given by S K Kon (vitamins and external metabolites), D I Arnon (micronutrients) and L Provasoli (growth factors of marine algae) E Baldwin's paper on biochemical perspectives and the need for more biochemists in marine research is timely

Papers on reef-building corals (C M Yonge) , productivity, patchiness and succession in plankton (W Rodhe *et al* , R Margalef, A C Hardy, L Tonelli and V Tonelli) , cell chemistry (E S G Barron, A Szent-Gyorgyi) , biological clocks (C S Pittendrigh, F A Brown, jun) show the variety of future problems That the section on behaviour consists of four papers as compared with twelve or thirteen of the other sections emphasizes our lack of knowledge W H Thorpe's excellent discussion of ethology indicates the vast amount of data awaiting discovery by simple observation assisted by aqualung, television and camera , and T H Waterman's contribution on underwater polarization patterns suggests many new ideas about plankton behaviour

If the biochemist is rare in marine biology how much more the geneticist Yet D L Ray shows that many species are suitable for genetical study, while papers by V L Loosanoff and Y Matsui point the way to controlled shellfish breeding and farming Geographical distribution, races, speciation of pelagic forms where there appears to be no barrier to gene flow, are challenging problems to all

This book is not just a list of problems for the future Most contributors base their speculations on accounts of present work, much of it unpublished Many contributions are of immediate concern and it is regretted that it has taken more than two and a half years to produce a book that one might expect —and hope—will soon be out of date Errors are few, the chief being the transposition of legends to text-figures 2 and 12 in Hardy's paper, while the last two lines to the legend of text-figure 1 of Bogorov's paper should read "continuous line indicates quantity of phytoplankton and broken line quantity of zooplankton" That the contributions are contained in 621 pages is largely due to the small type, but it remains easy to read and the tables and figures are well set out Non-marine biologists would do well to read this book for much of it has general biological implications

J A ALLEN

HETEROCYCLIC CHEMISTRY

Heterocyclic Chemistry

An Introduction By Prof Adrien Albert Pp viii+424 (London The Athlone Press, University of London, 1959 Distributed by Constable and Co , Ltd) 45*s* net

Six-Membered Heterocyclic Nitrogen Compounds with Three Condensed Rings

By C F H Allen, in collaboration with G M Badger, Brice Graham, G A Reynolds, James H Richmond, John R Thirtle, J A Van Allan and C V Wilson (The Chemistry of Heterocyclic Compounds a Series of Monographs, Vol 12) Pp xxii+624 (New York Interscience Publishers, Inc , London : Interscience Publishers, Ltd , 1958) 196*s*

CHEMISTS in general and students in particular have long been in need of a book of reasonable size on heterocyclic chemistry, but the digestion, selection and presentation of the subject have apparently daunted chemists, for Morton's book, published in New York in 1946, has been the only work of note to appear for many years This is not surprising, for our present detailed knowledge of heterocyclic chemistry must exceed in volume that of aliphatic or of aromatic chemistry, and the infinite variety of heterocyclic compounds must cause this difference to become ever greater A work by Prof Albert is therefore warmly welcome, and it is exceptionally interesting to see how he has approached the task of giving a concise account of this subject in 375 excellently printed pages

He has certainly broken completely away from the orthodox treatment, in which each class is usually discussed largely in the order syntheses, reactions, and finally structure on the basis of these two sections Instead, Prof Albert makes primarily an electronic structure approach to the various classes, and also discusses their physical properties, particularly spectra, ionization constants, oxidation-reduction potentials, and dipole moments in considerable (and very valuable) detail, relegating much of the synthetic side to smaller print This makes absorbing reading to the more advanced chemist, but one wonders whether students will both grasp and then continue to visualize the main bulk of heterocyclic compounds as "π-Deficient N-Heteroaromatics", "π-Excessive N-Heteroaromatics", and "π-Excessive O- and S-Heteroaromatics", which form the titles of the author's three main chapters ?

The author has dealt with the problem of condensing the sheer bulk of material partly by confining references to original literature to papers published since 1930, on the ground that these papers will provide sufficient references to earlier work The result can be unfortunate, for an account of fundamental work is often followed solely by a recent reference, which may record comparatively trivial modifications or extensions of the earlier work consequently the student may often lack the means to honour "the memory of the pioneers of heterocyclic chemistry" to which the book is dedicated It is a pity, furthermore, that although two distinct series of volumes on heterocyclic chemistry are still appearing, references are given almost solely to Elderfield's series, and the larger Weissberger series is almost ignored

The reviewer notes with interest the categorical statement that purines synthesized by building a pyrimidine ring on to an iminazole ring "have always introduced a hydroxy- or amino-group in the 6-position" (p 198) Mann and Porter, in 1945, synthesized by this method a number of 1 7-dialkylpurines which did not contain these groups in this position

The fresh approach, the clear lucidity of the presentation, and the author's personal enthusiasm have produced a book which chemists will read with great interest

The other volume, the twelfth to be published in the Weissberger series, is devoted solely to the chemistry of compounds having three six-membered rings fused together, the only hetero element being one or more nitrogen atoms The vast amount of information, carefully classified and coded in about 600 pages, vividly illustrates the reviewer's earlier comment on the expanse of our knowledge of heterocyclic chemistry The book deals with the chemistry of aza- and polyaza-anthracenes, -phenanthrenes and -benzonaphthenes , the amount of work entailed becomes apparent when one recalls that the monazaphenanthrenes alone form a group of five isomers Furthermore, tables are provided enumerating all the known simple and substituted members of each class up to 1952 This vast accumulation of knowledge has required the services of several chemists, and it concludes with an excellent chapter on "The Ultraviolet Absorption Spectra of Polycyclic Heterocyclic Aromatic Compounds" by Prof. G M Badger, of the University of Adelaide. This volume forms an outstandingly valuable addition to the Weissberger series.

F G MANN

Puzzle-Math

By Dr George Gamow and Dr Marvin Stern Pp 119 (London Macmillan and Co, Ltd, 1958) 8*s* 6*d* net

BOOKS of the 'mathematics for fun' type are often neither very mathematical nor very funny, but those who know some of Dr Gamow's earlier writings will expect this volume, in spite of its catchpenny title, to combine amusement with instruction, and they will not be disappointed The thirty-three problems are entertainingly set out, and solved by honest mathematical processes, involving little or no manipulative technique There are some 'chestnuts'—the three travellers with dirty faces, the fly between two approaching trains—but many of the problems are new or not widely known Is a motorist likely to be held up longer at a level-crossing if the track is double than if it is single ? When we ring for a lift, why does it seem to come in the wrong direction more often than not ? A bright student might easily be led to a better appreciation of the fundamental logic of mathematics by reading this cheerful little book T A A Broadbent

Transactions of the International Conference on the Use of Solar Energy

The Scientific Basis, held at Tucson, Arizona, U S A, October 31 and November 1, 1955 (Sponsored by University of Arizona, Tucson, Arizona, Association for Applied Solar Energy, Phoenix, Arizona, Stanford Research Institute, Menlo Park, California) Vol 1 The Available Energy Measurement of Radiation Pp xvi+135 Vol 2 Thermal Processes, Part 1, Section A, Flat Plate Collectors Pp ix+145 Vol 2 Thermal Processes, Part 1, Section B, High-Temperature Solar Furnaces Solar Power Pp v+146–264 Vol 3 Thermal Processes, Part 2, Solar House Heating Solar Water Heating Solar Stoves Solar Distillation Pp x+168 Vol 4 Photochemical Processes Pp xii+187 Vol 5 Electrical Processes Pp xii+132 (Tucson, Arizona The University of Arizona Press, 1958) 12 50 dollars the set

THESE Transactions, containing 85 scientific papers totalling 887 pages, represent one of the most valuable publications on solar energy research It is therefore all the more regrettable that although the conference at which these papers were presented was held late in 1955, publication has been delayed until the end of 1958, and moreover that there is no record of the valuable discussions that took place at the conference

The conference discussed the scientific basis of solar energy research and was followed by the World Symposium on Applied Solar Energy at Phoenix, Arizona The papers at the latter conference, which dealt preferentially with applications, were published in 1956, and the proceedings were reviewed by the writer (*Nature*, 178, 229, 1956), who also described in some detail the general features of both conferences soon after the meetings (*Nature*, 177, 110, 1956)

The present review is therefore restricted to consideration of a few aspects which have since been emphasized as important by the trend of solar energy research in the interval that has elapsed since presentation Interest in the flat-plate type of collector used for water-heating continues, but research is concentrated on the simplification of design and the use of metallic oxide surface coatings to restrict re-radiation of long wave-length and thus enable higher temperatures to be attained The high cost of the silicon photo-cell, which was then newly developed, has as prophesied been reduced to economic competition with electricity from dry cells and is coming into general use for portable radio and telephone equipment, not excluding such objects as space satellites The solar furnace sponsored by the French Government and described by M Trombe in Vol 2 is the most active achievement at present, and similar furnaces have been sponsored by the governments of other countries for testing materials to resist the thermal shock encountered in high-speed rocket flight and space travel

The Transactions are essential to those embarking on solar energy research, or wishing to ascertain the state of knowledge up to very recently Although there have been some remarkable developments since the conference, this set of volumes, which has been compiled by Prof Carpenter of the University of Arizona Observatory, constitutes a record of permanent value H Heywood

The Fundamentals of Statistical Reasoning

By M H. Quenouille (Griffin's Statistical Monographs and Courses, No 3) Pp 169. (London Charles Griffin and Co, Ltd, 1958) 24*s*

A GOOD short book on the basic principles and theory of statistical inference, expository of those parts of the subject on which statisticians are now generally agreed and objectively critical of some of the more controversial lines of thought, would be of great value Such a book appears to have been Mr Quenouille's aim, but he has had indifferent success Few subjects are in greater need of careful choice of every word, yet all too often the writing here is ambiguous or lacking in clarity For example, the opening paragraph of a chapter on testing hypotheses tends to obscure the important distinction between decision theory and scientific inference that Fisher and Barnard have so usefully emphasized in recent years Later in the same chapter "restriction" of errors of both the first and the second kind is said to be essential to a significance test of (surely "of deviations from" would be clearer) a null hypothesis

The first four chapters rapidly survey the concepts of probability, elementary distribution theory, estimation, and hypothesis testing The second half of the book is of a different order of difficulty and of much greater interest Here is an introduction to maximum likelihood and fiducial inference that could well form the basis of a more substantial text and could stimulate further research Mr Quenouille has a gift for devising the illuminating example He has evidently devoted much thought to fiducial distributions, and one wishes that he would undertake the systematic and critical account of this topic that must supplement Fisher's more intuitive approach if it is to attain its proper recognition Unfortunately, the present book is again unsatisfying, not only because of limitations of space but also because too often the reader cannot tell what is part of standard theory, what is a new contribution from the author (possibly deserving more explanation or more detailed reference to other publications), and what is a tentative suggestion for future exploration However, although one may question the wisdom of including some of this material in an introductory book, undoubtedly the more advanced student will value it D J Finney

The Nature of Experience

By Sir Russell Brain, Bt. (The Riddell Memorial Lectures, Thirteenth Series, delivered at King's College in the University of Durham, 12, 13 and 14 May 1958.) Pp. viii+73. (London: Oxford University Press, 1959.) 8*s*. 6*d*. net.

According to the trust deed, the Riddell lecturer is required to discuss "the relation between religion and contemporary development of thought". It is interesting to look back over past titles, and to see how successive speakers have interpreted their task. In this context, how well these discourses—the thirteenth—fit into the series, and maintain their tradition.

The theme is the field of perception, which the author explores with the object of attaining a view sufficiently comprehensive to restrain, if possible, the excessive specialization which is the outstanding characteristic of modern thought. The three lectures are entitled, (1) "Vision and Fantasy", (2) "The Nature of Perception", (3) "Symbol and Image". Some useful notes and references follow at the end.

Sir Russell is a leading neurologist, and one would expect to find a telling picture of mental processes; in the event, this knowledge is linked with rare aesthetic insight.

The first lecture reviews the conventional sense-impressions and their many contrasts with the structure of matter as the physicist knows it. The author believes that the qualities perceived are constructs of our own brains. Of particular interest is the account of abnormal states produced, for example, by mescaline. The second lecture contains a well-balanced review of the objections which have been raised against the writer's theory. In the last lecture, perhaps the most difficult, art is taken "as the embodiment of feelings in perceptual form", and thus embraces that subjective element deep in human nature which raises it, at times, to an image of the Divine.

F. I. G. Rawlins

Kingdom of the Octopus

The Life-History of the Cephalopoda. By Frank W. Lane. Pp. xx+287+48 plates. (London: Jarrolds Publishers (London), Ltd., 1957.) 30*s*. net.

Mr. Lane's book provides a collection of superb photographs for which the amateur naturalist and professional zoologist must be equally grateful. The full bibliography, clearly representing an immense amount of hard work, will be of value to the teuthologist, making available a number of obscure references and enabling him to examine for himself the provenance of the many curious and often entertaining legends and observations embodied in the text, and thus to make his own estimate of their scientific value.

The text has the inevitable failings of one written by an author who has no (and does not claim to have) specialist knowledge of the subject, and for whom it is therefore hard to assess the relative importance of the different facts and concepts which he has collected. Without such evaluation, however, verbally accurate statements can become misleading, and this fault is intensified, in Mr. Lane's book, by a tendency to dramatic presentation which results in important aspects of the subject receiving less full treatment than relatively trivial but striking details. A similar weakness is to be found in the references made to authors in the text. Mr. Lane is most careful to quote his sources; but, too often, equal weight is apparently given to the long-established findings of famous zoologists, to isolated observations scarcely yet verified, and even to statements, not necessarily accurate, introduced casually in the writings of specialists on other fields.

These failings will not diminish the interest which the rich anecdotal material and fine illustrations will rouse in the general reader; but, as a result of them, the book is scarcely suitable for the use of the student who seeks accurate and balanced information, and is not a book to be used for professional teaching without constant checking.

Anna M. Bidder

Die gesunden und die erkrankten Zahngewebe des Menschen und der Wirbeltiere im Polarisationsmikroskop

Theorie, Methodik, Ergebnisse der Optischen Strukturanalyse der Zahnhartsubstanzen samt ihrer Umgebung. Von Prof. W. J. Schmidt und Dr. A. Keil. Pp. 386. (München: Carl Hanser Verlag, 1958.) 48 D.M.

This book is undoubtedly a classic of its kind by authors who are world authorities in this particular field. It deals in the greatest detail with the normal structure of the calcified tissues of the teeth of man and animals, and then proceeds to a consideration of their structure in disease. The study of the calcified tissues of the teeth has always presented considerable difficulty. The two methods which have been used most are microradiography and polarized light. It seems a pity that no attempt has been made in this book to consider microradiography; but there is no doubt that the use of polarized light as here described and the interpretations given make it a very delicate method for this work. Much difficulty has been caused in the past by faults in interpretation arising from form birefringence and the possibility of birefringence arising from the organic matrices of some of these structures, but these are now all explained in detail, giving a proper scientific basis for further study.

This is the only authoritative work on the subject. It is beautifully produced and very well illustrated. No department, dental or zoological, dealing with the structure of normal or diseased teeth can afford to be without it.

A. I. Darling

Hundred Years of the University of Calcutta

Supplement. Pp. xviii+732+95 illustrations. (Calcutta: University of Calcutta, 1957.) n.p.

The Centenary History of the University of Calcutta was reviewed in these columns a little more than a year ago (*Nature*, **180**, 1152; 1957). This massive supplement adds a large volume of material, including descriptive accounts of the 274 colleges which are or have been affiliated with the University; similar accounts of the development and present state of the institutes and departments of the University; a select list of research publications; a list of University and College teachers in 1956; and a record of the speeches and ceremonies with which the centenary was celebrated in January 1957. There are nearly one hundred attractive photographs, chiefly of college buildings. This is the largest University in the Commonwealth—probably in the world—putting itself on record for posterity.

R. S. Aitken

RADIATION MEASUREMENTS TO 658,300 KM. WITH *PIONEER IV*

By Prof JAMES A VAN ALLEN and LOUIS A. FRANK
State University of Iowa, Iowa City

Introduction

THE present report comprises: (*a*) the radiation observations obtained with the U.S. deep-space probe *Pioneer IV*; (*b*) a comparison of these observations with those of *Pioneer III* and of the first Soviet cosmic rocket; and (*c*) an interpretative discussion.

The *Pioneer IV* programme was conducted under the same auspices as those for *Pioneer III*. The radiation detectors and the payload assembly were developed, calibrated and tested co-operatively by the Jet Propulsion Laboratory of the California Institute of Technology and by the State University of Iowa. The four-stage rocket vehicle and associated aspects of the enterprise were handled jointly by the U.S. Army Ballistic Missile Agency and the Jet Propulsion Laboratory, and the launching was conducted at the Atlantic Missile Range, Cape Canaveral, Florida.

The radiation 'package' was very nearly identical to the one flown[1] on *Pioneer III* except for one essential change—the Anton type 213 Geiger tube was encased in an additional shield comprising a closed-end cylinder of lead of thickness 4.0 gm./cm.^{2} and an inner cylinder of stainless steel of thickness 0.6 gm./cm.^{2} (Fig. 1). On the basis of extensive laboratory calibrations at the State University of Iowa, the respective Anton 302 Geiger tubes in *Pioneers III* and *IV* had identical characteristics (that is, effective dimensions, shielding, etc.) to within ± 10 per cent (see ref. 1 for further detail).

The purposes of the radiation experiments in *Pioneer IV* were as follows: (*a*) a re-survey of the intensity-structure of the zones of trapped radiation around the Earth, with special interest in temporal changes since December 6 and 7, 1958; (*b*) a crude determination of the absorptivity of the trapped radiation as a function of position in order to increase knowledge of its composition and spectral character; (*c*) a re-determination of the effective extent of the geomagnetic field; (*d*) a search for magnetically trapped radiation in the vicinity of the Moon; (*e*) a re-determination of the cosmic-ray intensity in interplanetary space; (*f*) a search in interplanetary space for 'blobs' of plasma containing particles sufficiently energetic to be detected by the present equipment.

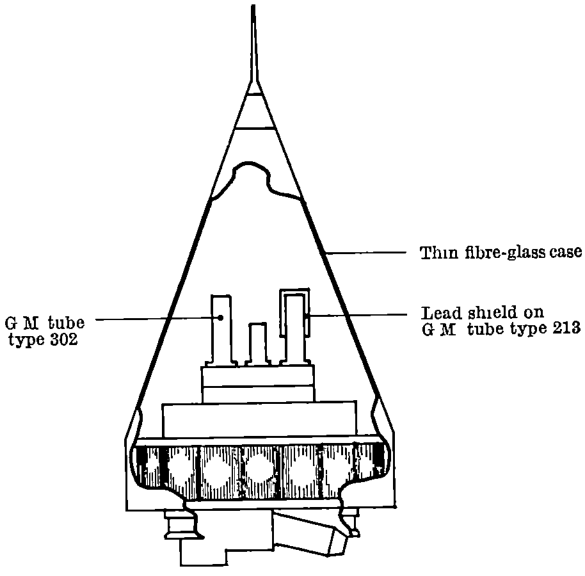

Fig. 1. Physical arrangement of radiation detectors in conical payload of *Pioneer IV*. Base diameter 23 cm. Total payload weight 6.1 kgm. The arrangement of *Pioneer III* was identical except for omission of the shield over the 213 tube

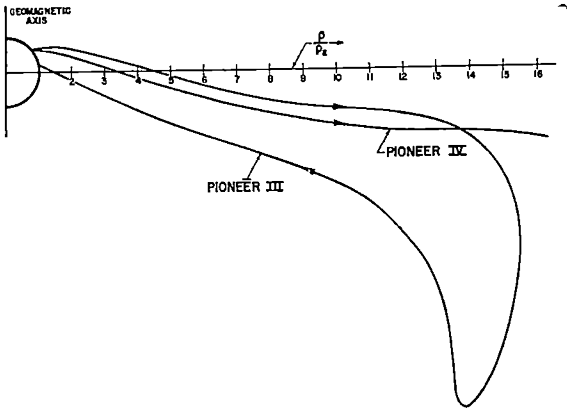

Fig. 2. Plots of the projection of the trajectories of *Pioneer III* and *Pioneer IV* on a geomagnetic meridian plane (centred dipole model). Unit of distance, ρ_E = 6,371 km.

Flight of *Pioneer IV*

Launch from Cape Canaveral, Florida (28.7° N., 80.7° W.) at 05.11 U.T. on March 3, 1959.

Burn-out velocity ('space-fixed'): 11.08 km./sec.

The positional co-ordinates as a function of time were measured by the Jet Propulsion Laboratory tracking array to an uncertainty of some ± 5 km. throughout the region of the trapped radiation and to a slowly increasing uncertainty thereafter. Table 1 lists representative values of the co-ordinates, and Fig. 2 gives a plot of the trajectories of *Pioneers III* and *IV* in the vicinity of the Earth.

Telemetry

The array of Jet Propulsion Laboratory telemetry stations comprised receivers at Cape Canaveral, Florida (5-ft. dish), near Mayaguez, Puerto Rico (10-ft. dish), and at Goldstone Lake, California (85-ft. dish), as before. In addition, there was the valuable Jodrell Bank 250-ft. dish, through the courtesy of Prof. A. C. B. Lovell. The following is a summary of flight periods during which usable radiation observations were obtained.

(*a*) Cape Canaveral
March 3 05 11–05 23 U T

(*b*) Puerto Rico
March 3 05 14–05 52 U T
07 23–15 32

(*c*) Goldstone Lake
March 3 11 58–21 03 U T
March 4 12 34–21 15
March 5 12 40–21 12
March 6 12 53–15 00

(*d*) Jodrell Bank
March 3 06 31–12 24 U T
March 4 07 52–08 08
08 23–08 43
10 42–12 52
March 5 05 41–12 58
March 6 05 42–12 59

From the point of view of the radiation experiment, the only serious loss of data occurred in the period 05 52–06 31 U T on March 3

Beginning at about 14 20 U T on March 6, the strength of the radio signal fell rapidly and no usable data were received after 15 00 U T In view of the rapidity of the decline (in spite of a trivial rate of change of distance) and of its occurrence at about the end of the expected life-time of the batteries, it is presumed that loss of signal at about $x + 82$ hr was due to exhaustion of the mercury batteries in the power supply of the payload The radial distance from the centre of the Earth was 658,300 km at 15 00 U T

Radiation Observations

Due apparently to a high-*g* shock which was recorded during the launching phase, the high scaling factor (2^{17}) element of the 302's scaling circuit did not function in flight This failure gives some cause for uneasiness concerning the proper operability of all other elements of the payload But we have been quite unable to find any evidence for any other malfunction and believe that the results reported below are trustworthy

In Fig 3 is plotted the true counting rate, *R*, of the 302 Geiger tube as a function of time Errors are insignificantly small except where error bars are drawn The constant counting rate beyond 11 10 U T continues without significant variation to the outermost limit of observations Also shown is the equivalent counting rate of the heavily shielded 213 Geiger tube Normalization of the counting rates of the two tubes was done in pre-flight laboratory tests by subjecting them (both unshielded) to identical exposure in a beam of hard X-rays The quasi-d c output of the 213 tube was measured by the audio-frequency of the subcarrier oscillator to which its amplifier was connected A substantial temperature correction was necessary and was made by comparison with another, similarly located oscillator the input of which was digital and the temperature coefficient of which was similar The temperature of the inner portion of the payload rose from a launching value of 15° C to an asymptotic value of 41 5 ± 1 0° C with a time constant of about 3 hr The 302 system had zero temperature dependence over this range In the lower left-hand corner of Fig 3 is plotted as a dashed line the ratio of the equivalent counting rate of the (shielded) 213 tube to that of the 302, this ratio is the apparent transmission, *T*, of the shield The absolute value of *T* is uncertain by some ± 25 per cent of its value due to a combination of systematic errors

In the time-period 06 31–06 53 U T the true counting rate of the 302 may lie either on branch *A* or on branch *B* Such an ambiguity is intrinsic to the characteristic curve of apparent rate versus true rate of the system (cf ref 1) and can be resolved only by auxiliary data The corresponding transmission curves are labelled *A* and *B*, respectively Further discussion is deferred to the next section

In Fig 4 the observations with the nearly identical 302 tubes of *Pioneer III* and *Pioneer IV* are shown as a function of radial distance from the centre of the Earth, ignoring differences of longitude and latitude

Table 1 REPRESENTATIVE VALUES OF POSITIONAL CO-ORDINATES OF *Pioneer IV*

(Bv courtesy of Jet Propulsion Laboratory)

* Nearest approach to the Moon (approx)

Discussion and Interpretation

The most striking features of Fig 4 are the immensely greater quantity of trapped radiation in the outer zone on March 3, 1959, than on December 6, 1958, and the detailed structure present, especially in the 60,000–90,000 km region It may also be noted that the observations by Vernov *et al*[2] with the Soviet cosmic rocket show that the situation on January 2, 1959, was similar to that on December 6 and 7, 1958 It is very suggestive that there was a substantial magnetic storm commencing at 02 15 U T on February 25 and that there were auroræ of strong intensity on February 25–28 and on March 1[3] A special study of this event by Trotter[4], of the High Altitude Observatory, makes it appear likely that at least three sequences of geophysical events starting on February 25, March 26 and April 23, respectively, were due to a solar *M* region In any event, it is noteworthy that the flight of *Pioneer IV* was preceded by five consecutive nights of strong auroral activity, whereas the periods preceding the flights of *Pioneer III* and of the Soviet cosmic rocket were especially

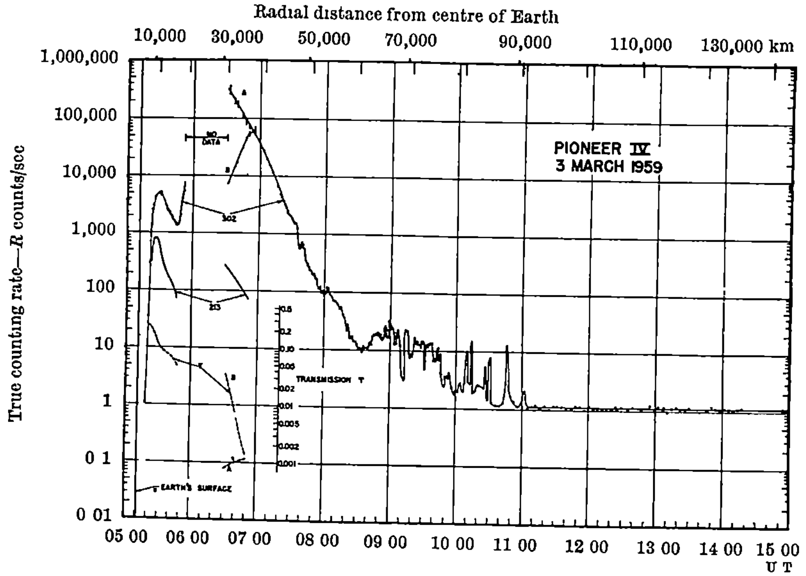

Fig 3 The counting rate observations during the early part of the flight of *Pioneer IV* (see text for further description of data)

quiet geophysical periods Hence we suggest that the great temporal differences shown in Fig 4 constitute the direct observation of the changes which occur in the outer radiation zone of trapped radiation following strong corpuscular emission from the Sun If this view be accepted then it appears that the *Pioneer IV* observations provide the most persuasive, direct evidence thus far available for the solar origin of (at least) the outer radiation zone

The inner peak of the *Pioneer IV* data (at 11,000 km) is about three times as intense as that of *Pioneer III* , but reference to Fig 2 and to a large-scale, corrected[5] plot as in Fig 5 of ref 1 shows that the inner zone was not significantly different on the occasions of the two flights From this fact it may be concluded that the inner zone, lying as it does in the region of strong geomagnetic field, is relatively well isolated from direct solar influence

The *A–B* ambiguity referred to in the preceding section in connexion with Fig 3 (and Fig 4) has not been conclusively resolved, but the following discussion strongly favours branch *A* as the correct one The work of Vernov *et al*[2] makes it appear likely that in the outer zone the effects recorded by a detector under more than 1 gm / cm^2 of absorber are due to bremsstrahlung from the bombardment of the outer skin of the payload by electrons of energies less than 100 keV and with a spectrum steeply rising toward lower energies If this be so, then we note that transmission curve *B* of Fig 3 not only has a quite unreasonable steepness but at its inner end has a value at least an order of magnitude greater than that measured in the laboratory with X-ray beams generated by electrons of such energies But transmission curve *A* is altogether consistent with this radiation situation

Adopting branch *A* and making use of our absolute X-ray calibrations of the 302 tube, we find that the omnidirectional flux of electrons of energy greater than about 20 keV was of the order of 1×10^{11}/cm^2 sec at 30,000 km radial distance on March 3, 1959

Also it is evident that the omnidirectional flux of electrons of energy greater than 200 keV did not exceed 1×10^8/cm^2 sec , of electrons of energy greater than 2 5 MeV did not exceed 1×10^6/cm^2 sec , and of protons of energy greater than 60 MeV did not exceed 1×10^2/cm^2 sec

The observations of *Pioneer IV* in the inner zone are unambiguous and show that about 30 per cent of the radiation recorded by the 302 in the lower fringe of the zone also penetrates an additional 4 0 gm /cm^2 of lead and 0 6 gm /cm^2 of steel The radiation becomes rapidly and progressively softer as one goes outwards from the Earth (Fig 3) On the basis of two recent rocket investigations into the lower fringe of the inner zone[6,7] and of our extensive *Explorer IV* and *Pioneer III* observations[1,8], we propose the following tentative composition of the trapped radiation present in the heart of the inner zone (altitude about 3,600 km on the geomagnetic equator) (*a*) electrons of energy greater than 20 keV —maximum unidirectional intensity $\sim 2 \times 10^9$/cm^2 sec steradian, (*b*) electrons of energy greater than 600 keV —maximum unidirectional intensity $\sim 1 \times 10^7$/cm^2 sec steradian , (*c*) protons of energy greater than 40 MeV —omnidirectional intensity $\sim 2 \times 10^4$/cm^2 sec The

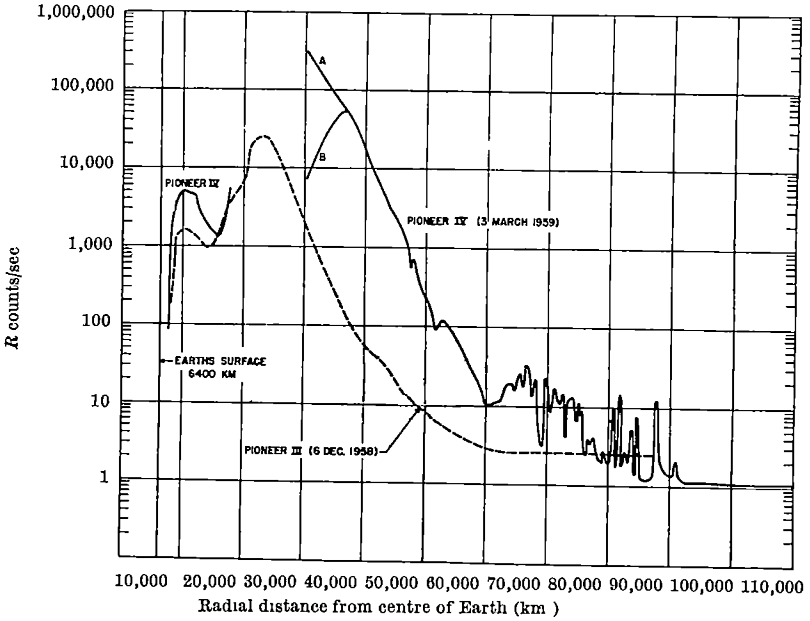

Fig 4 A comparative plot of the intensity data of *Pioneer III* and *Pioneer IV* on the same scale of radial distance but ignoring differences of latitude and longitude

latter two of these three figures are probably trustworthy to a factor of 2, the first one to a factor of 5 These results favour the neutron albedo hypothesis of origin of the inner zone of Vernov and others (cf discussion of ref 8), in respect to both the electron and proton components A valuable discussion of the proton component has been given recently by Hess[9] Some residual doubt may be felt as to the adequacy of the source function It should also be noted that there is a rapidly developing body of knowledge on the sporadic, though relatively frequent (order of once a month) arrival of solar protons having energies up to several hundreds of MeV and intensities up to several orders of magnitude greater than that in the quiet cosmic ray beam[10-13]

The conclusive identification of protons in the lower fringe of the inner zone[7] and the resemblance of their spectrum there to that expected on the neutron albedo hypothesis[9] has been accepted by many workers as conclusive evidence for the adequacy of this hypothesis The quantitative considerations of Hess have also added strongly to this point of view But it should be remarked that others, including Morrison, Gold and the present authors[8], have some uneasiness in accepting a trapping-lifetime of several years, as is necessary for the success of the neutron albedo hypothesis Thus, it is comforting to find that there is now an alternative source of protons (that is, direct solar emission) of suitable energy and intensity, provided a valid mechanism can be discovered for their admission into the inner zone The reader is also cautioned to await observations during the oncoming period of minimum solar activity for illuminating evidence on temporal changes in both inner and outer radiation zones Such a programme of observation is being undertaken by this laboratory

Radiation Intensity Beyond 92,000 km

Pioneer IV provided a total of 45 hr of observation of the counting rate of the 302 Geiger tube in the range of 92,000–658,300 km from the centre of the Earth (The counting-rate-meter circuit of the 213 was not sufficiently sensitive to provide a reading at any time during this portion of the flight) The mean counting rate was calculated over each interval of time during which 256 (2^8) counts were recorded The distribution of counting rates in the 695 such intervals (each of about 4 min duration) has been studied in detail and it has been found that during no one of these intervals did the counting rate differ with statistical significance from the overall mean value of 1 090 ± 0 003 counts per sec

A broader scale survey of the mean counting rate during larger segments of the trajectory was obtained by tabulating the times at which 'flips' of the major scaler ($2^{13} = 8{,}192$ counts per major 'flip cycle') occurred The constancy of the counting rate during observed periods encouraged us to also 'count through' the unobserved periods of time, during which the payload was below the effective horizons of the receiving stations During the longest such period six major flips were missed, and during the other two such periods four major flips were missed if it be assumed that the counting rate did not differ markedly when under observation and when not under observation The results of this process are shown in Table 2 The trustworthiness of the tabulated counting rates during unobserved periods rests on *a posteriori* evidence as follows On the assumption that the unobserved counting rates did not differ markedly from the observed ones, it is found in Table 2 that the unobserved counting rates differed by less than 1 per cent (that is, to within statistical uncertainty) from the adjacent, observed ones The precision of this agreement in all three of the cases under consideration gives one a strong feeling of assurance that the counting rate of the 302 did not differ significantly at any time in the interval 92,000 to 658,000 km (March 3, 11 10 U T, to March 6, 15 00 U T) from its mean observed value of 1 090 ± 0 003 counts per sec Several valuable conclusions follow from this analysis and are described in subsequent sections

Paucity of Energetic Plasma in Interplanetary Space during March 3-6, 1959

On the basis of Table 2 and the foregoing discussion, it appears that, to high accuracy, the apparatus did not encounter any solar plasma containing particles sufficiently energetic to register efficiently on the 302 tube during some 76 hr of interplanetary flight

Since the burden of evidence for the origin of the outer radiation zone of the Earth requires that plasma fly outwards from the Sun sporadically, it must be concluded that there happened to be a notable absence of such plasma during this period This finding is especially striking in view of the strong geophysical activity during the preceding week An alternative view is that the acceleration of the components of the plasma to sufficiently high energies to be registered efficiently by our equipment occurs only in the geomagnetic field. The 302 tube in the present arrangement had an efficiency of about unity for protons of energy greater than 30 MeV., an efficiency of the order of unity for electrons of several MeV. energy, and an efficiency of the order of 10^{-4} to 10^{-6} for electrons in the hundreds to tens of keV. energy-range (by way of their bremsstrahlung).

Hence, during the 76 hr. in question the time-integrated flux of the higher-energy electrons and protons could not have exceeded 100/cm.^{2} in an isolated burst during any one of the 695 observed 4-min. intervals, could not have exceeded 1,000/cm.^{2} in an isolated burst during any one of the three unobserved periods which had a duration of some 10 hr. each, and could not have exceeded 2×10^5/cm.^{2} if distributed (with quite unbelievable uniformity) over the 76-hr. period. The corresponding figures for 60 keV. electrons, for example, are 4×10^5 times as great.

Lack of Influence of the Moon

Pioneer IV's closest approach to the centre of the Moon was 60,149 km. at about 23.00 U.T. on March 4 (Table 1). The telemetered signal was not being received at that time (see section on "Telemetry" and Table 1). But observations were obtained as close as 61,700 km., and Table 2 and the accompanying discussion make it exceedingly unlikely that any significant change of counting rate occurred at any place in the vicinity of the Moon. The quantitative discussion of the preceding section is applicable here also. The geometrical shadow of the Moon on the apparatus was, of course, negligible. Hence, this result suggests as an upper limit to the Moon's magnetic moment a value comparable to that of the Earth. This high an upper limit is, of course, of little interest in the light of other, probably more definitive, knowledge which favours a much smaller value.

The Soviet cosmic rocket passed much closer to the Moon than did *Pioneer IV*, but unhappily the radiation intensity was unreadable at that range.

None the less, the determination of the Moon's magnetic moment by investigating its trapped corpuscular radiation on near approaches remains a technique of potential value. It will doubtless be wise to use a detector of the lowest feasible energy threshold and of the highest feasible sensitivity.

Re-determination of Interplanetary Cosmic-ray Intensity

On the basis of Table 2 and of our best present values of absolute geometric factor and efficiency of the 302 Geiger tube, we find for the interplanetary value of the omnidirectional cosmic-ray intensity $J_0 = 1.8 \pm 0.3$/cm.^{2} sec. during the period March 3–6, 1959.

It may be noted that this value is one-half of that measured[1] on December 6 and 7, 1958, with *Pioneer III*. On the basis of a recent re-study of *Pioneer III* data, Snyder[14] presents evidence that *Pioneer III* did not reach a sufficiently great distance to be entirely free of the influence of the geomagnetic field.

The *Pioneer IV* observations to very much greater distances (out to 103 Earth radii) are not subject to this uncertainty. Hence, we have considerably greater confidence in the new value quoted above, though it should be understood that the counter will record protons of energy as low as 30 MeV. and electrons of energy as low as 2.2 MeV. In any event, the measurement provides a solid upper limit to the total primary cosmic-ray intensity in the general astronomical vicinity of the Earth during early March 1959.

Using balloon-borne equipment of discriminating character, McDonald[15] finds primary unidirectional cosmic-ray intensities (corrected to zero atmospheric depth) at geomagnetic latitude 55° on July 2, 1958, as follows:

(*a*) Protons of energy greater than 280 MeV. 0.0950 ± 0.0070/cm.^{2} sec. steradian

(*b*) α-Particles of energy greater than 158 MeV./nucleon 0.0149 ± 0.0012

(*c*) Sum of (*a*) and (*b*) 0.1099

An interesting comparison results from multiplying McDonald's sum of 0.11/cm.^{2} sec. steradian by 4π to obtain an estimate of the omnidirectional intensity of primary cosmic rays remote from the Earth. The result is $J_0 = 1.38$/cm.^{2} sec. In so far as McDonald has been able to eliminate fast, downward-moving albedo, his implied J_0 has the nature of a lower limit.

Vernov and Chudakov[2] report a value of 2.3 ± 0.1/cm.^{2} sec. on January 2, 1959.

Effective Extent of the Geomagnetic Field

Our original interpretation of the *Pioneer III* observations[1] included the conclusion that the geomagnetic field loses its ability to trap charged particles at about 10 Earth radii. Snyder's discussion makes it appear that this was too small a value. The *Pioneer IV* observations (Fig. 4) indicate that geomagnetic trapping is significantly present out to as far as 14 Earth radii, at least on a specific occasion. The loss of geomagnetic trapping efficiency is, of course, a loosely defined concept and there are doubtless marked fluctuations in the radiation regions at the outer fringes of the Earth's field.

Terrestrial Ring Current of Dolginov and Pushkov

Measurement of the scalar magnetic field intensity with the magnetometer in the Soviet cosmic rocket on January 2, 1959, provided results of very great interest[16] in the present connexion. The observed scalar field intensity fell gradually and progressively farther below the curve representing the extrapolation of the surface field (using an eight-coefficient harmonic expansion and assuming a curl-free field outside the solid Earth) in the radial distance range 14,000–21,000 km. At 21,000 km., the experimental curve was some 700 gammas below the 'theoretical curve' (about 1,200 gammas). At greater radial distances the experimental curve rose toward the theoretical one and approximated to it beyond 26,000 km. These results imply a westward-flowing ring current having the maximum value of the apparent current density at about 21,000 km. radial distance from the centre of the Earth. By comparison with Fig. 4 of the present article, it is seen that the most intense portion of the ring current lies in the inner side of our outer peak of radiation intensity and indeed in just the region in which the gradient of the volume density of charged-particle kinetic energy has its greatest value. The understanding of the detailed relationship between the Dolginov–Pushkov ring current and the trapped radiation now becomes one of the most challenging and timely problems of geophysics[17].

It may be speculated that the modification of the geomagnetic field by the ring current at about 3 Earth radii influences the structure of the radiation zones and perhaps contributes to the existence of the 'slot' between the two zones.

We are indebted to Dr. William H. Pickering, director of the Jet Propulsion Laboratory, for the opportunity to conduct the present work and for financial support, and to Messrs. Henry Curtis, Dan Schneiderman, John Casani, and Frederick Smith and Dr. Conway Snyder, all of Jet Propulsion Laboratory, for many courtesies during the course of the work.

Overall management of the programme rested with the National Aeronautics and Space Administration.

RADIOCARBON DATING OF THE PILTDOWN SKULL AND JAW

By Prof. H. de VRIES
Natuurkundig Laboratorium, Rijks-Universiteit, Groningen

and

Dr. K. P. OAKLEY, F.B.A.
British Museum (Natural History)

Introduction
(K. P. Oakley)

In 1950 it was shown[1] by the fluorine method of relative dating that the Piltdown mandible and cranial bones were considerably younger geologically than the Lower and Middle Pleistocene fossils said to have been found at the same site. Assuming that they were genuine finds, the hominoid remains were not older than Upper Pleistocene, but it was noted that drill-holes into the teeth revealed that they were "apparently no more altered than the dentine of recent teeth from the soil"[2]. In 1953, Dr. J. S. Weiner, reviewing this evidence in the light of anatomical considerations, suggested that the mandible was that of a recent ape which had been broken and stained to resemble a fossil, and the teeth artificially abraded to suggest wear through the human type of mastication. According to his hypothesis, the fraudulent jaw-bone had been placed in the Piltdown gravel pit so as to appear associated with fragments of a thick human cranium of presumed antiquity.

Determination of the organic content and re-determination of the fluorine content of these specimens, together with evidence obtained from a detailed anatomical analysis of the teeth, confirmed this hypothesis[3] (Table 1). The mandible had the composition of modern bone, whereas the cranial fragments were very slightly 'fossilized'.

In 1953–55, the possibility of dating the Piltdown bones absolutely by the radiocarbon method was not seriously considered because it would have involved total destruction of the specimens to provide the minimum quantity of carbon (2 gm.) then demanded by radiocarbon laboratories for a single determination. During the past four years, improvement of technique has made it possible to attempt radiocarbon dating on the basis of much smaller quantities. With the agreement of Dr. E. I. White, keeper of palæontology, powder samples of the Piltdown mandible and right parietal bone were submitted to Prof. H. de Vries after repeated washing in acetone and then in warm water (at 70° C.) which was carried out under rigorous conditions in the Department of the Government Chemist. The nitrogen content of powder samples of these bones proved to be the same before and after submission to this extraction treatment, proving their freedom from nitrogenous contaminants (for example, glue, gelatine, celluloid). Their nitrogen content represents the *bone protein* (collagen), which is not removable by acetone or warm water. This is the material which provided the carbon the radioactivity of which has now been measured.

Table 1

	Fluorine (per cent) (1950)	Fluorine (per cent) (1953)	Nitrogen (per cent)	Carbon (per cent)
Piltdown mandible	0·2 ± 0·2	<0·03	3·9	14·5
Piltdown cranium	0·2 ± 0·1	0·10 ± 0·01	1·4	5·3
Fresh bone		0·03 ± 0·01	4·0	14·0

The Radiocarbon Results
(H. de Vries)

The sample of Piltdown mandible was burnt without any further pretreatment. The sample of the Piltdown skull (right parietal) was given a treatment which will be described in more detail elsewhere. It was dissolved in hydrochloric acid; the fraction which was not precipitated by alkali was dated. Both samples gave a very small amount of carbon dioxide, corresponding to about 0·1 gm. of carbon. Therefore, the precision is not what it could have been, but certainly good enough for the present purpose. Though controversial dates on bone have been published, our recent experience indicates that the conclusions drawn from the present results are trustworthy (Table 2).

Table 2

Piltdown mandible (*GRO* 2204)	500 ± 100 years*
Piltdown skull (*GRO* 2203)	620 ± 100 years*

Expressed in terms of statistical probability, there is 1 chance in 3 that the ages of these specimens lie outside the stated limits, but only 1 chance in 20 that they lie outside the ranges 500 ± 200 and 620 ± 200 years, respectively.

* Allowance has been made for the Suess effect (that is, the age was calibrated against nineteenth-century wood).

Comments on the Results
(K. P. Oakley)

The results are satisfactory. In the first place they confirm that the Piltdown jaw is geologically quite recent. (Even since the exposure of the hoax in 1953 and 1955, statements have appeared in print maintaining that it is a Pleistocene fossil, considerably more ancient than the cranial bones.) The indication that this mandible is a few centuries old raises the question of its origin. When Sir Wilfrid Le Gros Clark established that it was the jaw-bone of a modern orang-utan (and therefore came from Borneo or Sumatra), it was assumed to be a zoological collector's piece. Is it not very unlikely that an orang-utan jaw-bone falling into the hands of a collector would prove to be several centuries old ? In fact, this is not so improbable as might be supposed. One possibility is that the specimen was obtained from a dealer in ethnographical material. Prof. G. H. R. von Koenigswald has pointed out that the Dyaks of Borneo have been known to keep orang-utan skulls as fetishes or trophies[4] in their long-houses for many generations. Mr. Tom Harrisson, curator of the Sarawak Museum, recently sent to the British Museum (Natural History) a photograph of an orang-utan skull, with mandible, which is said to have been preserved for twenty generations—about 400 years (Fig. 1). However, the chances of an ethnographical dealer obtaining such a highly treasured object directly from living Dyaks are regarded by Mr. Harrisson as negligible. On the other hand, he has pointed out that a number of sub-recent bones of orang-utan, obtained in Sarawak in various circumstances, were brought back to Britain in 1875 by A. H. Everett and briefly described[5]. Some were obtained from caves the contents of which were washed by Chinese gold workers. At least one of the specimens (No. 55) appears to have been a trophy skull. Part of Everett's collection (including the last specimen) was presented to the British Museum (Natural History). All the orang-utan skulls and jaws listed as received by the Museum in 1879 can be accounted for ; but Mr. Harrisson believes that Everett brought much more material to Britain, and what became of it is unknown. Did it pass into the hands of dealers ?

Comparison between one of the 'sub-recent' orang-utan jaw-bones in the Everett Collection (No. 100 in Everett's list, recorded as "doubtfully from a cave" in Sarawak ; registered as *ZD*.84.10.30.2) and the Piltdown jaw-bone has brought out a number of points of resemblance. Not only is the nitrogen content of the 'antique' Bornean specimen likewise undiminished (4·6 per cent, determined by Mr. G. Ross in the Central Laboratory, Department of Zoology, British Museum (Natural History) ; he has reported 4·0–5·3 per cent nitrogen in other recent Hominoid bones) but also the surface of the bone is in the same finely cracked condition, which was difficult to account for if the Piltdown specimen came from a modern zoological collection. Attempts to reproduce the appearance of the Piltdown jaw by artificial treatment of modern bones failed in just this respect. The condition of the collagen fibres, revealed by the electron-microscope, indicated that it had *not* been boiled.

The radiocarbon dating of the cranial bones has confirmed that they also are Post-Pleistocene in age as indicated in the report of 1955 (p. 257). In 1953, it was thought that they might have been genuine finds which had served as the nucleus of the hoax ; but as soon as it was proved (as reported by Dr. G. F. Claringbull and Dr. M. H. Hey in 1955) that all the cranial fragments had been artificially stained to match the gravel, it became clear that they were fraudulent introductions at the site, so the possibility of their being of Pleistocene age could be entirely discounted. The phosphatic matter of these cranial bones has been partially altered to gypsum. This is only explicable if they had been artificially stained by an acid iron sulphate solution. Experiments showed that this alteration only occurs if the bone has the porosity due to partial loss of organic matrix. Thus the Piltdown cranial bones are evidently of moderate antiquity. Presumably they were fragments of a skull selected on account of its unusual thickness from among a series obtained in the excavation of some ancient burial ground. The fluorine content of the unaltered portion of their bone substance also indicates that they are of some slight antiquity ; but unless one knows the source of a bone, precise relative dating by fluorine content is impossible. However, in many British and foreign cemeteries bones less than a thousand years old can be found with the same fluorine content (0·1 per cent).

Fig. 1. Orang-utan skull with mandible kept as a fetish in a Dyak long-house seventy miles from Kuching and said to be twenty generations (about 400 years) old

Although the difference in the radiocarbon ages of the cranial bones and mandible is less than might have been expected in view of their contrasting states of preservation, it should be borne in mind that whereas a bone that has been buried in the ground for a few centuries may have become porous and 'sub-fossil' (with some absorbed fluorine), a bone of equal antiquity that has been preserved in air, for example on the floor of a dry cave, in a building or in a reliquary, may have retained the composition of 'recent' bone.

Summary. Radiocarbon dating has confirmed that the Piltdown skull (human) is Post-Pleistocene, probably less than 800 years old; and that the Piltdown mandible (orang-utan) is younger rather than older, although possibly several centuries old. It is shown that these findings are not inconsistent with the skull being in 'sub-fossil' condition whereas the mandible (of very different origin) has the preservation of 'recent' bone.

DISORGANIZATION OF THE SECONDARY STRUCTURE IN PROTEINS EXPOSED TO IONIZING RADIATIONS IN THE SOLID STATE

By Dr. PETER ALEXANDER, L. D. G. HAMILTON and Dr. K. A. STACEY
Chester Beatty Research Institute, Institute of Cancer Research, London, S.W.3

LITTLE is known of the chemical and physical changes which occur when proteins are exposed to ionizing radiations under conditions where the effect is due to ionization within the protein molecules, that is, by 'direct' action. Detailed physical chemical studies have only been made on protein irradiated in solution when the reaction is indirect and due to free radicals. Most investigations of the direct effect have been confined to following the effect on their biological properties. It has been known for nearly fifteen years (cf. Lea[1]) that the inactivation of dry enzymes by ionizing radiations is exponential with dose, which suggests that one event leads to loss of activity. The amount of energy which has to be supplied before this single reaction occurs is normally between 50 and 200 eV. per molecule, depending on the enzyme. Quantitatively this suggests that nearly every primary ionization must be effective in destroying the biological activity. A primary ionization in an organic substance brings with it far-reaching chemical changes which usually affect several groups, but it seems highly improbable that the inactivation of all enzymes can be attributed to the chemical modification of a few amino-acid residues.

Biochemical studies[2] have shown that for many enzymes only a small part of the protein molecule is necessary, and that a large proportion of the amino-acid residues can be modified without loss of activity. Energy transfer processes which were recognized in organic macromolecules[3] cause preferential attack of some groups; but the effect is not sufficiently selective to provide a mechanism for the inactivation of all enzymes by a single random event.

In a detailed study of the changes produced by irradiating solid crystalline bovine serum albumin (Armour Laboratories) containing 4–6 per cent of water with 2 MeV. electrons, in the absence of oxygen we have found that the first effect of irradiation is to disorganize a large part of the molecule. This alteration in structure is not dependent on covalent chemical changes which follow ionization, but is the result of a breakdown of many secondary valency bonds brought about by a single event which occurs on average for every 45 eV. deposited and can therefore be associated with a primary ionization. The occurrence of a process of this type was predicted by Platzman and Franck and provides a mechanism for the inactivation of heat-labile enzymes of all types by ionizing radiations.

Opening up the Molecule

On irradiation the sedimentation behaviour of the bovine serum albumin in the ultracentrifuge changes[4], and the decrease in normally sedimenting material follows an exponential relationship (Fig. 1), with a Do (dose required to change 63 per cent of all molecules) of $6\cdot5 \times 10^6$ rads. This corresponds to an energy of 45 eV. per molecule, which has to be supplied to affect on average one molecule. Change in sedimentation implies an alteration in molecular weight or in frictional resistance determined by the internal structure of the molecule. Light-scattering measurements show that with a dose sufficient to alter the sedimentation of 75 per cent of the molecules, the average molecular weight of bovine serum albumin rises only from 69,000 to 90,000. The ultracentrifuge measurements therefore indicate that a single event which occurs on average for every 45 eV. of energy supplied changes the shape of the molecule. The assumption that the material sedimenting normally is native protein that has not been affected at all by radiation is confirmed by chromatography.

Evidence that radiation 'opens up' the molecule is provided by changes in the chemical reactivity of the constituent amino-acid residues. Bovine serum albumin contains seventeen disulphide groups per molecule, but at the isoelectric point none of these can be reduced to $-SH$ groups[5], or oxidized with peracetic acid to sulphonic acid groups[6] under standard conditions. These groups are sterically inaccessible, but at pH values away from the isoelectric

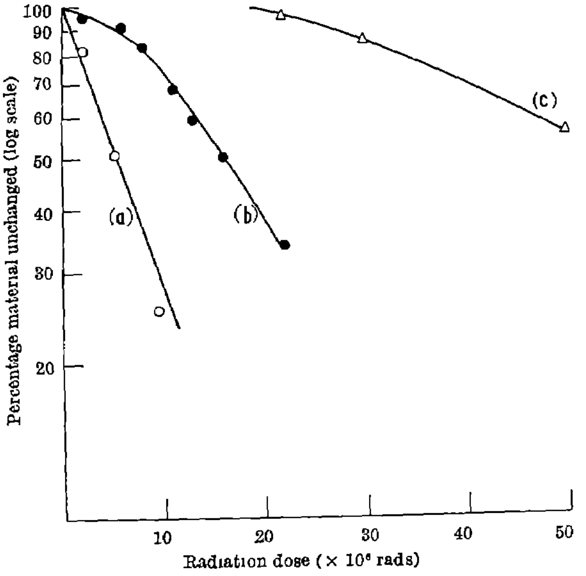

Fig 1 Effect of irradiation of 2 MeV electrons on some physical properties of bovine serum albumin

a, Fraction of bovine serum albumin showing changed sedimentation behaviour in the ultracentrifuge, *b*, fraction of bovine serum albumin insoluble in water, *c*, fraction of bovine serum albumin insoluble in *M*/15 phosphate buffer (*p*H 7)

point, or following denaturation, some become available for reaction Exposure to 4 *M* guanidine hydrochloride at the isoelectric point makes available 70 per cent of the total present, and this is further increased at alkaline *p*H values On the other hand, a maximum of only 50 per cent are revealed by heat denaturation[6]

Irradiation of the solid protein progressively increases the number of disulphide bonds available up to a maximum of 50 per cent (Fig 2) (at the highest doses some of these are destroyed, but within the dose-range studied this is negligible) From the irradiated bovine serum albumin a fraction can be separated which is no longer soluble in water, and dissolves only in salt solution In the water-soluble fraction an increasing proportion of the disulphide bonds (up to 30 per cent) is revealed, and by applying a correction, on the basis of the ultracentrifuge measurements, for the presence of unchanged native material, the number of available groups in the molecules affected by radiation can be calculated (Fig 2) This first radiation change can be described as an opening up of the molecule which changes the frictional properties but not the molecular weight, and reveals five disulphide bonds normally hidden Since this change is associated with a single reaction which occurs when an average of 45 eV have been left in the molecule, it can probably be ascribed to the production of one primary ionization

Changes following a Multi-Hit Dose Relationship

Another radiation effect is to render the protein insoluble in water, while remaining soluble at high and low *p*H values and in salt solutions To avoid 'trapping', the insoluble fraction is determined by measuring the protein which comes out of solution on dialysing out the *M*/15 phosphate buffer (*p*H 7) in which the irradiated protein is completely soluble Fig 1 shows that in the production of insolubility there is a pronounced threshold with dose, and it fits accurately a 'two-hit' curve This protein has a greatly increased light-scattering molecular weight with average values ranging up to 350,000, but is highly poly-disperse. These aggregates are not broken up, that is, the average molecular weight is unchanged, by solvents breaking hydrogen bonds or disulphide bonds, and the cross-links joining the molecules in the aggregates do not therefore involve either of these bonds An interpretation consistent with all the facts is that a second ionization still further disorientates the secondary structure of the molecule and thereby changes its solubility behaviour, enabling cross-links to be formed between molecules In this extensively modified protein following the second ionization approximately half the disulphide bonds are available

Further irradiation does not reveal any more disulphide bonds, but it does render the protein insoluble even in salt solution (curve *C*, Fig 1). This heavily irradiated material dissolves only in 4 *M* guanidine hydrochloride Probably extensive chemical alterations now involving about 5 per cent of all the amino-acid residues made extensive intermolecular hydrogen bonding possible

Chemical Changes

Chemical analysis of the irradiated protein for nine amino-acids shows that the disappearance of amino-acids (the nature of the products was not established) was linear with dose, but that the sensitivity of the constituent amino-acids varies Cystine and dicarboxylic acids were the most sensitive , the aromatic and the basic amino-acids came next in sensitivity and proline was the least affected by radiation of those studied However, the total range was less than a factor of three, for example, 10^8 rads affected 18 per cent of the cystine, 12 5 per cent of the histidine and 8 per cent of the proline Thus, after a dose sufficient (that is, 45 eV /molecule) to 'open up' the protein, only one molecule in five will have a single cystine residue changed, one in six one histidine residue, and only one in two will have lost a carboxyl group

The possibility that main-chain polypeptide bonds are broken was tested by looking for low molecular

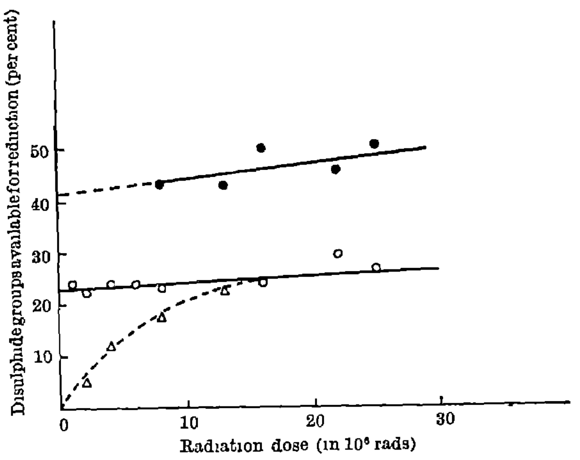

Fig 2 Effect of radiation on the number of disulphide bonds in bovine serum albumin which can be reduced at the isoelectric point with β-mercapto-ethylamine

—△—, For water-soluble fractions (that is, including the molecules that have not been affected by radiation), —○—, for water-soluble fraction after correction for unchanged protein on the basis of the ultracentrifuge data, —●—, for fraction insoluble in water, but soluble in salt solution weight fragments which could be recovered by dialysis of solution of heavily irradiated protein in 4 M guanidine hydrochloride. To guard against the possibility that broken fragments do not become detached because they are linked to the main molecule by disulphide bridges, the irradiated protein dissolved in guanidine hydrochloride was oxidized with peracetic acid, which breaks all disulphide bonds under these conditions. As no dialysable fragment could be found even after a dose of 2.5×10^8 rads it can be concluded that main-chain breaks play no part in the disorganization of the secondary structure.

Other chemical changes due to irradiation are the formation of carbonyl groups[7] and of additional SH groups, as well as of a new amino-acid which has the same chromatographic behaviour as α-amino-*n*-butyric acid.

The presence of oxygen during the irradiations did not alter the first stage of 'opening up' or the destruction of amino-acids. However, the protein is rendered insoluble in water at lower doses and the greater radiation sensitivity of dry enzymes in oxygen[8] may be due to the increased tendency for aggregation, or the production of main-chain breaks, which is facilitated by oxygen.

Mechanism of Enzyme Inactivation

Although bovine serum albumin has been studied by us in greatest detail, irradiation of solid trypsin, lysosyme and γ-globulin produces a very similar sequence of events, and we believe that the pattern outlined above applies generally to globular proteins. We interpret the changes which occur in a protein molecule by an ionization produced within it by an atomic particle as a two-stage process. First, the introduction of a positive charge disrupts the secondary structure over a large part of the molecule and introduces a new configuration. Secondly, the group in the molecule that has become ionized undergoes a chemical change. The latter are not randomly distributed and energy transfer processes increase the probability of damage in certain amino-acid residues. But these effects are not very selective and there is no indication that one particular type of side-chain will be altered in every protein molecule that had suffered an ionization. This precludes the possibility that loss of activity can be due to these chemical effects, and it seems much more plausible to relate inactivation to the initial disturbance of secondary structure as this is an immediate consequence of the ionization. An explanation is provided why ionizing radiations are much more effective (on a dose basis) in inactivating enzyme[9] than ultra-violet light or the indirect action of ionizing radiation (that is, H and OH radicals). Both these processes attack the protein chemically and alter side-chains, but they cannot disorganize the secondary structure directly.

We suggested tentatively[10] that the sudden introduction of a positive charge breaks down induced dipoles and that the resulting temporary opening of hydrogen bonds allows the protein molecule to adopt a configuration having a lower free energy. The difficulty is to provide a mechanism by which the electric disturbance spreads over a significant part of the protein molecule. Platzman and Franck[11] were led from purely theoretical considerations to postulate that an ionization within a protein molecule changes the internal hydrogen bonding. They have discussed the probable range of the electrical disturbance in considerable detail and conclude that some fifteen to twenty hydrogen bonds can be severed in this way. Not enough is known of protein structure to predict whether the breakage of this number of hydrogen bonds is sufficient to produce the observed disorganization.

We wish to thank Mr. W. H. T. Davidson, of the Research Laboratories of Tube Investments, Ltd., for carrying out the irradiations, and Dr. D. Rosen for the ultracentrifugation.

This investigation has been supported by grants to the Chester Beatty Research Institute from the British Empire Cancer Campaign, the Jane Coffin Childs Memorial Fund for Medical Research, the Anna Fuller Fund, and the National Cancer Institute of the National Institutes of Health, U.S. Public Health Service.

ORIENTATION OF ANIMALS TO POLARIZED LIGHT

By DR. H. KALMUS

Galton Laboratory, University College, London

WORK done or published during the past year concerning the orientation of animals—mainly arthropods—to the plane of polarization of light indicates the emergence of two different and, up to a point, contradictory approaches to these visual reactions. What may be called the orthodox view gradually developed since von Frisch's original discovery in 1948 of the ability of bees to orientate themselves with respect to the plane of polarization, has been ably summarized in a review article by Stockhammer[1]. He considers the various types of arthropod eyes to be analysers and, in particular, thinks that the analysing faculty is not situated in the dioptric parts but depends upon special arrangements of visual pigments in the receptor cells which, like a polarizing screen, would combine the properties of analysis and absorption

Quite different conclusions have been drawn by Baylor and Smith (*Apis*)[2], Bainbridge and Waterman (*Mysidium*)[3], Burdon-Jones and Charles (*Littorina*)[4], as well as by Kalmus (*Aedes*, *Drosophila*, *Thaumatomyia*)[5], who considered that the orientational behaviour of these various animals in the presence of polarized light might be explained either by purely external mechanisms, for example, by brightness patterns resulting from unequal scattering or reflexion from environmental objects, or by similarly unequal refraction from some faces of the dioptric apparatus, such as the surface of the eye Neither of these interpretations requires analysing arrangements in the receptors

The hypothesis that the rhabdomers of insect ommatidia are absorbing analysers is supported by the electro-physiological results and electron microscopical work quoted by Stockhammer[1] , it has been further strengthened by the beautiful electron micrographs of insect eyes by Fernández-Móran[6], confirming that each rhabdomer is built up of numerous rod-shaped or tubular units which are oriented in regular array with their long axes more or less at right angles to the long rhabdomer axis In an opposite pair of rhabdomers in any ommatidium the rods or tubules show a similar orientation, but in adjoining rhabdomers their orientation differs The orientation of the rods in the rhabdoms of neighbouring ommatidia may follow a regional pattern At the level of the basement membranes 7–9 single sheathed nerve fibres exist in every ommatidium, indicating that separate signals might originate and be transmitted from each rhabdomer Some of Móran's figures show indeed a striking similarity to the 'star' model of an ommatidium, which von Frisch proposed many years ago for its analysing properties , and provided it can be shown that the dichroitic visual pigment is incorporated into the rhabdomer pattern in a regular and orientated manner, a physical basis would seem to exist for the assumption that the rhabdomers of insect eyes are indeed analysers Thus equipped, the eyes of a bee should be able to distinguish between various areas in the blue sky which, during the daytime, are fairly characteristic in their degree of polarization and direction of the plane of polarization, and which, according to von Frisch's experiments, they learn to recognize , and navigating bees might use this information, rather as they use the position of the Sun when it is directly visible to them

A transversal arrangement of rod-shaped structures seems to be of wide occurrence in the rhabdomers of arthropods, and a similar organization, found in the visual elements of the squid *Loligo*[7], may occur in the molluscs But in the rods and cones of vertebrates, the orientation of the structures to which the visual pigments are presumably attached is quite different and unsuitable for the detection of the plane of polarization of light impinging in the physiological direction

Reactions to polarized light striking the rounded surface of some types of bulgy eyes at a skew angle can be expected to produce specific orientational effects in the absence of retinal analysers Castle (quoted by Stockhammer[1]) has shown that a primitive type of such orientation occurs even in the absence of eyes, for example in fungi : the cylindrical sporangiophores of Phycomyces growing upwards in a culture respond unequally to light of equal intensity but different planes of polarization If light from two such sources strikes a sporangiophore from opposite directions it will bend, showing that the horizontally polarized light has a stronger effect than the vertically polarized light provided that the former is not the weaker in intensity by more than 10–15 per cent In compound eyes, perception of polarization in oblique rays of light is only possible if the optical isolation of the individual ommatidia is not absolute, and if some light initially deviating from the ommatidial axis can produce visual effects Such a situation is admitted by Stockhammer (quoting Waterman) to exist in *Limulus*, but denied by him for *Drosophila*, *Cladocera* and *Mysidium* It may nevertheless occur in some commoner situations , for example, when insects fly under large areas of strongly polarized light from the sky bordering directly on dark areas in their visual field

Selective reflexion of polarized light by structures in the environment of an animal provides another means of orientation, by producing brightness patterns Such patterns being objective can be made visible to the human eye In Baylor and Smith's[2] experiments, bees were released into a flat chamber covered with clear glass and illuminated only by plane polarized light from above Those bees which crossed the box tended to run preferentially at right angles to the plane of polarization when the bottom of the chamber was covered with some dark and reflecting material, whereas over a white paper they did not show any directional preference Under unpolarized light, preferential directions of running were observed over a directionally biased dark reflecting surface Bees running under a source of polarized light over the dark bottom of the chamber showed orientation even when the light could not strike their eyes directly, regardless of whether they were running on the dark surface or upside down on the glass A periscope-like arrangement showed that the intensity of the light reflected at sighting angles of 10–30° from the dark surface under polarized light varied greatly in different directions , and it is in fact easy to demonstrate that reflexion of polarized light from such a surface at low angles is strongly directional

Making use of optomotor responses, I showed[5] that various dipterous (*Aedes*, *Drosophila*, *Thaumatomyia*) and other insects followed the rotation of a 'Polaroid' sheet under vertical illumination only when they were moving on or over dark reflecting material, but did not react against a bright background The existence of an objective brightness pattern in the light reflected at low sighting angles was again demonstrated , and movement of this pattern can explain the optomotor responses

Bainbridge and Waterman[3] showed that orientational responses to polarized light of the marine crustacean *Mysidium gracile*, previously reported by them, occur only when the water containing the animals is made turbid by the addition of yeast No significant results were obtained in carefully purified sea-water The orientational responses of *Mysidium* under a vertical source of polarized light thus seem dependent upon the discrimination by these crustaceans of differences of intensity in light scattered horizontally

Burdon-Jones and Charles[4] have shown that photonegative winkles of the species *Littorina littoralis*[4] move along the plane of polarization of light from an overhead source when it strikes them directly from above, even when the animals are allowed to crawl on a small ball in such a way that no light is reflected from the substrate The snails, however, orientate themselves equally well when their eyes are shielded from direct light and the only light they can see is reflected from the substrate Photopositive individuals orient themselves at right angles to the plane of polarization Burdon-Jones and Charles believe that in either situation the snails orient themselves with respect to a pattern of light and shade, perhaps arising from the Fresnel laws of refraction of plane polarized light, and that the animals do not possess any special powers of analysis whereby they could discern the polarized light in another way

Our knowledge of orientational behaviour in polarized light is as yet too scanty and insufficiently integrated to permit of a general resolution of the apparent contradictions, and in fact it is not at all certain that similar mechanisms operate in all situations where polarized light has been shown to produce orientational effects Some suggestions might, however, be useful One might distinguish between phototactic responses of animals which are correlated with the plane of polarization of light and the more complex perception and consequent utilization of polarization patterns in the blue sky as inferred for the bee by von Frisch Indirect directional effects of overhead sources of polarized light striking certain structures in the natural or experimental environment or in the dioptric apparatus and resulting in objective brightness patterns might frequently provide a sufficient explanation for the orientational behaviour of animals whether they in fact possess retinal receptors with analysing properties or not On the other hand, it is rather difficult to see how orientation with respect to small areas of blue sky could occur without such receptors. However, in many situations brightness gradients and polarization patterns in various parts of the blue sky are associated, and bees might in fact orient themselves to the former Furthermore, reflexion patterns caused by sunlight will often have their maximum brightness in the same azimuth as the Sun itself and the same applies to polarized light from a small area of sky reflected in a substrate. Thus the position of the Sun might be perceived by a bee directly or, when the Sun is invisible, its azimuth might be inferred from a brightness maximum in an area of the sky or a reflecting background The reactions of *Littorina* in the different conditions described above conform with such an explanation and might perhaps be taken to support this speculation

Another aspect of the orientation to polarized light might be mentioned finally, namely, its role in the life of the animals It is probably safe to assume that many of the observed reactions are merely experimental artefacts However, it is possible that, in other instances, orientation to sources of polarized light—however it works—may be of great ecological importance Progress in this field will depend on the careful weighing of evidence from such diverse techniques as electron microscopy, electrophysiology, photometry and not least from observations of the animals concerned

OBITUARIES

Sir Ian Clunies-Ross, C M G.

Sir Ian Clunies-Ross, chairman of the Commonwealth Scientific and Industrial Research Organization (Australia), died on June 20 in Melbourne, Victoria, in his sixty-first year He was born at Bathurst, New South Wales, and educated at Newington College, Sydney He graduated as bachelor of veterinary science from the University of Sydney in 1921 and was awarded the degree of doctor of veterinary science of that University in 1928 After graduation he was awarded a Walter and Eliza Hall Veterinary Research Fellowship and undertook postgraduate studies at the London School of Tropical Medicine and at the Molteno Institute, University of Cambridge In 1928 he went to Japan for parasitological studies at the Institute of Infectious Diseases at Tokyo Imperial University

In 1925 Clunies-Ross was appointed lecturer in parasitology in the University of Sydney, and in the following year Council for Scientific and Industrial Research parasitologist When the C S I R McMaster Animal Health Laboratory was established in 1931 through the munificence of Sir Frederick McMaster, Clunies-Ross was appointed as the first officer-in-charge He held this position until 1937, when he was appointed Australian representative, and later chairman, of the International Wool Secretariat in London

Early in his career Clunies-Ross specialized in veterinary parasitology—a much-neglected subject in Australia at that time He saw clearly its great economic significance, especially to the sheep and wool industry, and applied himself to it so effectively that he quickly became one of the world's leading scientists in that field Although most of his work dealt with helminthiasis of sheep, his interest ranged widely among parasitological problems of other domestic animals and of man He brought to all his work a broad outlook and a depth of scientific understanding which inspired his colleagues and immediately won the confidence of the livestock industries Between 1923 and 1937 he published some sixty articles as sole author and a further fifteen as senior author , in addition, he was co-author of a text-book on the parasitic diseases of sheep

Realizing at the outset that the clarification and definition of the multiple and diffuse problems of ovine helminthiasis were essential if effective means of therapy and prophylaxis were to be devised, he instigated widespread surveys of the incidence and distribution of the major worm parasites of sheep, and of the associated climatic and other factors which determined their clinical significance Thus, for the first time a sound basis was laid for studies on epidemiology, host-parasite relationships and selective anthelmintic treatment He and his colleagues followed up with great vigour and enthusiasm the advantage this clearer understanding of the problem gave them, and progress flowed from it rapidly

Among his many outstanding contributions, Clunies-Ross was the first to record the effect of copper sulphate on closure of the œsophageal groove in sheep This opened up a new approach to anthelmintic treatment It was he who, by well-planned field trials, removed the fears of graziers that more intensive stocking of sheep on improved pastures would result in heavy losses from parasitism This led him to investigate the effects of improved pastures on the quantity and quality of wool production It was widely held that the well-being of the Merino and the quality of its wool depended on extensive, highly selective grazing, and that intensive grazing on the narrow range of species in sown pastures would result in coarse and inferior fleeces Clunies-Ross clearly demonstrated that not only can Merino sheep tolerate intensive grazing but also that they respond to the higher nutritional levels of sown pastures by producing much heavier fleeces with little change in fibre diameter

Clunies-Ross was an inspiring research leader He had the capacity to see problems clearly, to ask the crucial questions and to find ways of answering them effectively by laboratory or field experimentation His interest in veterinary research, however, and his choice of problems was always greatly influenced by his genuine love of animals This is well exemplified by the work in tick-paralysis of dogs, which was one of his most original and successful investigations He was then living in a part of Sydney where many hundreds of pet dogs died annually from the disease He was so moved by their suffering and by the distress of their owners that, in addition to all his other work, he took it upon himself to study this problem also Within three years he elucidated the epidemiology of the disease, traced its cause to a toxic factor in the salivary gland of the engorging female tick (*Ixodes holocyclus*), and prepared an antitoxic serum of high curative value This was typical of him , his interest was not in gaining new knowledge for its own sake but for the use which could be made of it Having once gained it, he used to the full his great gifts as a writer and public speaker to explain its significance to all who could apply it with advantage

Clunies-Ross's active personal research had to be laid aside when he joined the International Wool Secretariat Although he was appointed professor of veterinary science in the University of Sydney in 1940, he had little opportunity for scientific work, as he was called upon to serve during the war years as director of scientific personnel in the Commonwealth Directorate of Manpower and with the Department of War Organization of Industry as an adviser on the pastoral industry The War interrupted his scientific career, but it gave him opportunities to use his unique knowledge of Australian agriculture and his outstanding powers as a speaker and publicist to encourage and assist the remarkable growth of science and education in Australia during the years which followed In 1946 he joined the Executive Committee of the Council for Scientific and Industrial Research, and in 1949, when the Council was reorganized as the Commonwealth Scientific and Industrial Research Organization, Clunies-Ross became its first chairman He continued to maintain his close interest in the wool industry and played a large part in procuring the funds which enabled C S I R O to build up a major effort in sheep and wool research and wool textile research Throughout the pastoral industries his many friends had confidence in his judgment, and with their help and with the backing of the Government he had the satisfaction of seeing, towards the end of his life, a large body of scientists working enthusiastically on many problems of great national importance The major contributions which C S I R O has made to the agricultural development of Australia have been largely due to his outstanding and inspiring leadership

Clunies-Ross had many interests outside his scientific work The field of education was one in which he played a big part, and he was outspoken on the need for retaining breadth and liberalism in education He stressed repeatedly the dangers inherent in the increasing specialization of modern scientific and technological careers He played a large part in persuading the Government to set up the Murray Committee on Australian universities and made a major contribution to its outstanding report He was deputy chancellor of the University of Melbourne and a member of the Council of the Australian National University For many years he was active in the work of the Australian Institute of International Affairs and was well known as a public speaker on foreign affairs He was particularly interested in the relations between Australia and its northern neighbours As chairman of the International House of the University of Melbourne, a hall of residence in which Australian and overseas students live together, he was instrumental in making the idea a reality

Clunies-Ross was made C M G in 1954, and in the same year he was created a knight bachelor He was a foundation Fellow of the Australian Academy of Science He was awarded the honorary degrees of doctor of laws by the University of Melbourne, and doctor of science by the Universities of New England and Adelaide He is survived by Lady Clunies-Ross, three sons and one daughter

At the memorial service held in Scots Church, Melbourne, shortly after his death, Prof J D McCaughey, Master of Ormond College, University of Melbourne, made a fitting tribute to his memory He expressed in these simple terms the feelings of his many friends and colleagues throughout Australia and overseas "But in and through these achievements, it is Ian Clunies-Ross the man whom we remember with admiration, with respect and with affection to-day His capacity for work must have been enormous to die at sixty is young, yet into those years was packed an astonishing variety and depth of interests He lived a heavily committed life , yet, I suppose, that many of us in this Church think of him, with gratitude, as one who had time for friendship He accepted us with a smile It must have been given to few who have lived so fully, yet to be loved by so many"

F W G WHITE
D A GILL

Dr V Korenchevsky

DR V KORENCHEVSKY, who died suddenly on July 9, was born in 1880 in Russia and graduated from the Imperial Military Medical Academy in St Petersburg in 1903 After military service in Manchuria during the Russo-Japanese War, he worked in Metchnikoff's department at the Pasteur Institute in Paris and in Pavlov's laboratory in St Petersburg

In 1911 he was appointed professor of experimental pathology in the Imperial Military Medical Academy and remained there until the Revolution His disagreement with the policy of the newly formed Soviet Government made it necessary for him to leave St Petersburg and he escaped to south Russia, where he served as a doctor with the White Army for about a year After the defeat of the White Army he made his way to England and in due course became naturalized

During 1929–45 he was a member of the staff of the Lister Institute Afterwards he established the Oxford Gerontological Research Unit, with the support of funds provided by Lord Nuffield, and remained there until his retirement in 1952

The bulk of Korenchevsky's work between the Wars was primarily endocrinological and was concerned with studies of the effect of sex and thyroid hormones, separately and in combination, not only on the reproductive organs but also on the other organ systems of animals of different ages His work was characterized by a very close attention to detail, the use of first-class histological techniques and insistence on the need for healthy experimental material Korenchevsky regarded this work as a necessary preliminary to provide a rational basis for use of hormones in mitigating some of the degenerations which occur with ageing

Dr Korenchevsky will be especially remembered, however, for his pioneer achievements in stimulating interest in the field of gerontological studies His own concern with the problems of ageing went back to the early years of the century when he visited Russian infirmaries for old people, and during his stay with Metchnikoff in Paris he worked on the effects of gastro-intestinal autointoxication He always remained convinced of the value of Metchnikoff's theory, and he reaffirmed his belief in the importance of autointoxication as an ageing factor in several recent publications

By the late 1930's he felt that the change in the climate of opinion, for which he had been waiting, had come and that vigorous efforts to emphasize the need for gerontological research might at last be effective He therefore set out with the intention of developing an International Association of Gerontologists which would be responsible for investigations in all branches of the subject His efforts were just beginning to bear fruit when the outbreak of the War in 1939 brought them to an end for the time being

After the War, his retirement from full-time active laboratory work allowed him to extend his campaigning even more vigorously He was an outspoken advocate of the importance of gerontology, and in his missionary ardour he sometimes appeared intolerant of the ideas of others But any irritation engendered by his interventions were always more than outweighed by their stimulant effect, and it was clear to everyone that he was never seeking any personal advancement but only the benefit to his chosen subject which recognition might bring The results of his lifetime of strenuous effort will be found not so much in his large series of careful scientific publications as in the numerous national societies for the study of problems of ageing throughout Europe and the Americas, in the International Association of Gerontology and in the enhanced status which the subject has now acquired

P L KROHN

NEWS and VIEWS

Chief Scientist to the Ministry of Power

Dr C M. Cawley, C B E.

DR C M CAWLEY, C B E, has been appointed chief scientist to the Ministry of Power in succession to Sir Kelvin Spencer, who has retired from the public service Dr Cawley, who is fifty-two, has been at the headquarters of the Department of Scientific and Industrial Research for the past six years, where he has been responsible for administering general policy in relation to the work of the Department's research stations, and to grants made by the Department to the universities and other bodies, for the promotion of research and the training of research workers He is a University of London graduate with first-class honours in chemistry and joined the Scientific Civil Service in 1929, serving on the staff of the Fuel Research Station until 1953 He will take up his new appointment at the Ministry of Power in the early autumn

Ministry of Supply Appointments

Dr N. J L Megson

DR N J L MEGSON has been promoted to be deputy chief scientific officer and appointed director of materials, research and development (air) at the Ministry of Supply Headquarters Dr Megson studied chemistry at the University of Birmingham under Prof G T Morgan He obtained his B Sc in 1923 and his M Sc in 1925 He joined the Chemical Research Laboratory, Department of Scientific and Industrial Research, in 1927, as head of the Synthetic Resin Section and carried out fundamental and applied work on various aspects of polymers, particularly in the phenolic resin field

On the outbreak of war he was appointed to the Ministry of Supply as advisor on plastics and later became assistant director in charge of the Advisory Service on Plastics, Rubber and Paints, concerned with development and application of new and special materials for a variety of Service equipment In 1949 he was awarded the degree of D Sc by the University of Birmingham for a thesis entitled "Polymer Investigations" He became head of the Chemistry Department, Royal Aircraft Establishment, in 1951, responsible for research and development of non-metallic materials associated with aircraft and airborne equipment Dr Megson is the author of fifty or sixty publications, including a book, "Phenolic Resin Chemistry", and he has recently been awarded the Gold Medal of the Plastics Institute He succeeds Dr H Sutton, whose direct contribution to and sponsorship of work on light metals for aircraft construction has brought him deservedly wide appreciation

Dr B G Dickins, C B E

DR B G DICKINS, who has been promoted to be chief scientific officer and appointed as director general of atomic weapons in the Ministry of Supply, brings to that post wide knowledge of operational problems and experience of weapon development He obtained a first-class honours degree in physics in the University of London and entered the Civil Service in 1932 He served at the Royal Aircraft Establishment until 1936 and was then transferred to Air Ministry Headquarters He was attached to the Royal Air Force Station at Biggin Hill as the scientific officer associated with the now well-known air defence experiments which were initiated by Sir Henry Tizard and his committee When he returned to the Air Ministry he was still closely concerned with air defence problems and in addition became joint secretary of a committee under Sir George Thomson to advise the Government on the practicability of an atomic bomb He was for a time responsible for arranging the officially sponsored work in various universities In 1941, he was put in charge of the newly formed Operational Research Section, Bomber Command, which analysed the Command's operations from all aspects and made contributions to the knowledge available to the Command staff, which led to increased efficiency and improved operational methods After the War, at Air Ministry Headquarters, he assisted in the establishment of the peace-time organization of operational research in the Royal Air Force During 1948–1952 he was director of technical personnel administration in the Ministry of Supply where his main work was the planning of recruitment of technical staff particularly in the fields of guided weapons and atomic weapons He returned to the Air Ministry as deputy to the scientific adviser, whose duties were to advise the Air Staff on the influence of the new weapons on strategy and tactics and to direct operational research He was then appointed director of guided weapon research and development in the Ministry of Supply, where he was responsible for much of the Ministry's research and development work on guided weapons for all three Services In a reorganization in 1958 his work was concentrated on the development of the British intermediate range ballistic missile

Mr P. A Hufton

Mr P A Hufton has been promoted to become chief scientific officer and appointed head of the Aerodynamics Department at the Royal Aircraft Establishment in succession to Mr L F Nicholson, who is the new director general of scientific research (air), Ministry of Supply Mr Hufton graduated in engineering at the University of Manchester in 1933 and obtained his M Sc degree a year later He joined the Aerodynamics Department of the Royal Aircraft Establishment in December 1934 and after working for a short period on low-speed research, transferred to the Aerodynamic Research Flight where he remained until March 1946 Before the War, he worked part-time with C N H Lock at the National Physical Laboratory on propeller theory and experiments During the War he was responsible for take-off and landing research, particularly for heavily loaded aircraft, rocket-assisted take-off, development and flight testing of high-lift devices, and work on carrier landings for the Royal Navy In the spring of 1946 he moved to the Aeroplane and Armament Experimental Establishment at Boscombe Down as superintendent of performance He returned to the Aerodynamics Department, Royal Aircraft Establishment, Farnborough, in October 1953, in charge of the Supersonics Division and moved to the Royal Aircraft Establishment at Bedford as head of the Aerodynamics Division in September 1957 A year later Mr Hufton became chief superintendent of the Royal Aircraft Establishment at Bedford in succession to Mr L H G Sterne

Chemistry at the Royal College of Science and Technology, Glasgow :

Prof F S Spring, F R S

Prof F S Spring, who is retiring from the chair of chemistry in the Royal College of Science and Technology, Glasgow, graduated at the University of Liverpool under Sir Ian Heilbron and received his first appointment in 1930 in the University of Manchester, where he remained for sixteen years After Sir Ian Heilbron moved from Liverpool to the chair of organic chemistry in Manchester he and Spring worked in close collaboration over a number of years and made notable contributions to our knowledge of the chemistry of the sterols, vitamin D, and the triterpenes During this period Prof Spring's work was particularly associated with the structure of ergosterol and calciferol, and with the β-amyrin group of triterpenes Prof Spring was elected to the Freeland chair of chemistry at the Royal Technical College (now the Royal College of Science and Technology) in Glasgow in 1946 Here he has developed a flourishing school of research in the chemistry of the triterpenes and of certain heterocyclic systems Prof Spring was a Tilden Lecturer of the Chemical Society and was elected a Fellow of the Royal Society in 1952

Prof. P. L. Pauson

Dr Peter Ludwig Pauson, who has been appointed to succeed Prof Spring, graduated at the University of Glasgow with first-class honours in chemistry in 1946, and proceeded to Sheffield as holder of a Henry Ellison Research Fellowship There he worked under R D Haworth on purpurogallin and was awarded the degree of Ph D in 1949, having already shown his versatility by giving good service as temporary assistant lecturer in inorganic chemistry He spent the next four years in the United States, first as assistant professor at Duquesne University, Pittsburgh, then as Research Fellow successively at the University of Chicago and at Harvard It was then that he discovered the novel 'sandwich compound', dicyclopentadienyl–iron, usually known as ferrocene The interest aroused by this substance and its relatives was such that, less than four years later, Dr Pauson could publish a timely review article on work in this field, with eighty-eight references He returned in 1953 to the University of Sheffield, where he now holds the post of reader, vigorously pursuing the investigation of these remarkable substances, both as quite exceptional cases of metallic co-ordination and as organic aromatic systems of a new type

Nuclear Physics at the University of the Witwatersrand :

Prof. J. P. F. Sellschop

Dr J P F Sellschop has been appointed to the chair of nuclear physics at the University of the Witwatersrand as from July 1 He will continue to be director of the University's Nuclear Physics Research Unit, to which position he was appointed in 1956 Prof Sellschop, who at the age of 29 becomes the youngest professor in the University, is at present in Britain carrying out research at the Atomic Energy Establishment at Harwell for six months He is a member of the Research Advisory Committee of the

Atomic Energy Board and represented the Union at a seminar on atomic energy and its educational problems which was held in Saclay, France, under the auspices of the International Atomic Energy Agency in July. Prof. Sellschop was also an official delegate to the second International Conference on the Peaceful Applications of Atomic Energy in Geneva last year. Born in Luderitz, South West Africa, Prof. Sellschop received his early education at Christian Brothers' College, Pretoria. He then became a student at the University of Pretoria and received the B.Sc. degree there *cum laude* in 1950. After working at the National Building Research Institute in Pretoria for two years he was awarded an H. B. Webb scholarship and enrolled in the Merensky Institute of Physics at the University of Stellenbosch and in 1952 received the degree of M.Sc. *cum laude*. He then joined the Bernard Price Institute of Geophysical Research, later successfully reading for the Ph.D. degree in the nuclear physics group of the Cavendish Laboratory, Cambridge, as holder of a postgraduate scholarship awarded by the Shell Company of South Africa Ltd. in 1954.

Microbiology at Sheffield: Prof. S. R. Elsden

DR. SIDNEY REUBEN ELSDEN has been appointed to the newly created chair of microbiology in the University of Sheffield, as from October 1. Dr. Elsden was educated at the Cambridge and County High School for Boys and the University of Cambridge. He graduated B.A. in 1936 and obtained first-class honours in both parts of the Natural Sciences Tripos. During 1937–38 he worked under Dr. Marjory Stephenson in the Department of Biochemistry at Cambridge and was then appointed assistant lecturer, and later lecturer, in physiology in the University of Edinburgh. In 1943 Dr. Elsden joined the scientific staff of the Agricultural Research Council's Unit of Animal Physiology at Cambridge. He went to Sheffield in 1948 as senior lecturer in microbiology in the Department of Bacteriology and in 1952, when the University created a separate Department of Microbiology, Dr. Elsden was appointed head of the new Department. He has also been honorary director since 1952 of the Agricultural Research Council's Unit of Microbiology, which is housed in his Department. Dr. Elsden's Department has received generous support from the Rockefeller Foundation, and the Agricultural Research Council Unit has also received a grant from the Kellogg Foundation.

New Commonwealth Institute Building

PLANS for a new building for the Commonwealth Institute were made public on June 17. The new premises, which will replace the present accommodation in the Collcutt building in South Kensington, will be erected on a 3¼-acre site at the southern end of Holland Park, fronting Kensington High Street, at an estimated cost of £725,000. Work will start next spring and is scheduled for completion in 1962, when the removal of the Institute from its present building will be necessitated by Government plans for the expansion of the Imperial College of Science and Technology. The new Institute will consist of a main exhibition block with a wing on the western side. In the wing will be housed offices, a restaurant, a reception centre and dining space for visiting school parties. A large reception room for the Commonwealth Students' Club and for conferences and social occasions, a reference library and reading-room, a cinema to seat between 450 and 500, and a gallery specially designed for temporary art and other exhibitions are also included in the plans. The architects are Messrs. Robert Matthew and Johnson-Marshall. The Commonwealth Institute is the major centre in the United Kingdom for information about the Commonwealth nations and their Dependencies. Founded as the Imperial Institute in 1887, it has occupied its present accommodation in the Collcutt building since 1893. The name was changed from 'Imperial' to 'Commonwealth' Institute by the Act of 1958.

The British Non-Ferrous Metals Research Association

THE opening of the latest addition to the laboratories of the British Non-Ferrous Metals Research Association by Sir Alexander Fleck on May 13 is a further step in the progress of an Association which has grown in activity and reputation ever since it was first established some thirty years ago. This reputation in the field of non-ferrous metallurgy is acknowledged not only in Britain but also abroad. The restoration of the laboratories after serious war damage suffered serious delays, and with the increase in the Association's work and the resulting congestion, the decision was taken in 1957 to complete the building plans which had been formulated some twenty years earlier. The block now opened adds some 12,500 sq. ft. of floor space, bringing the total to about 53,000 sq. ft. It contains new corrosion laboratories, a large new metal finishing shop, extensions to the physics laboratories and to the foundry. Together with these a new council chamber and badly needed offices for the senior staff add considerably to the administrative amenities.

The Metropolitan-Vickers Nuclear-Metals Laboratory

IT was with the view of ascertaining the effects of irradiating metals that Metropolitan-Vickers Electrical Co. Ltd. decided to extend the existing facilities of the Research Department by building a Nuclear-Metals Laboratory. The Laboratory is equipped for the examination and testing of irradiated components and materials ranging up to a complete fuel element having an activity of the order of 10 kc. It is provided with two large concrete caves, and a train of five interconnected lead-walled cells is used to receive large irradiated objects. Essentially the caves are constructed of barytes concrete blocks. The air in the caves is arranged to be maintained at a slightly lower pressure than that in the open laboratory, thus ensuring that no air-borne radioactive dust can escape. Remote control manipulators enable the operations to be carried out inside the caves from outside the walls. The new laboratory will primarily be engaged on work for the Associated Electrical Industries—John Thompson Nuclear Energy Co., Ltd., and on work under contract for the U.K. Atomic Energy Authority. The scope of work will be concerned not only with investigations into the irradiation effects on constructional materials such as graphite and steel of various types, but also with establishing the behaviour of metals such as magnesium, zirconium, beryllium, etc., and of thermal and electrical insulation materials. A highly organized health physics service is maintained to safeguard the operating staff against all the hazards involved.

Sponsored Research in Great Britain

FACILITIES for sponsored research in Great Britain were increased by the formation in 1957 of the Arthur D Little Research Institute which has laboratories at Inveresk, Midlothian The Institute is a non-profit-making organization registered in Great Britain as a company under the Friendly Societies Act, and although the two concerns are separate, it operates in close association with a similar group in the United States, Arthur D Little, Inc , of Cambridge, Mass The Institute has now issued its first annual report from which readers may gain some idea of the scope and objects of the new venture With Lord Bilsland as chairman of the Board of Directors, and with Dr F N Woodward as director of research, the Institute has been concerned with several projects, all of which are being treated with special reference to the fundamental scientific background The results will normally be given open publication when the work is complete, and interim accounts of the various projects are given in this annual report These projects include investigations of the sodium derivatives of sucrose and of their condensation with a variety of organic halogen compounds, studies on the mechanism of the formation of isotactic polymers, the development of rapid methods for assessing the effectiveness of potential corrosion inhibitors, studies on the mechanism of inhibition of corrosion by electrochemical methods, and investigations into the modification of wood cellulose by chemical methods In addition, the report refers to lectures, publications and other scientific activities organized by the staff of the Institute It will be of great interest to all those who wish to know more about this new development in sponsored research and its place in the general organization of research in Great Britain

Nuclear Studies in the United Kingdom

THE Science Department of the British Council has issued its third list (May 1959) entitled "Nuclear Studies" This is a concise catalogue of courses in pure and applied sciences concerned with the use and development of nuclear energy It is issued primarily as a guide for the overseas student who wishes to undertake specialized, formal training in the United Kingdom Consequently it includes only full-time courses, generally of one week or more in duration, and is not concerned with research topics or with the courses which may be regarded as forming part of a normal first-degree course Although the list has appeared too late for application to be made for many of the courses during the academic year 1959–60, it serves to direct inquiries for courses in 1960–61 Further information can be obtained from the Science Department of the British Council, 65 Davies St , London, W 1

Building Research in New Zealand

IN recent years, a number of fields of investigation relating to the building industry in New Zealand have been pursued independently in various organizations and laboratories in which the main interests have been in quite different fields The Dominion (Chemical) Laboratory has investigated paints and local building materials , the New Zealand Forest Service has carried out work on timbers, both indigenous and exotic, suitable for building , the Pottery and Ceramics Research Association has investigated the appropriate use of brick constructions for earthquake conditions , and the Dominion Physical Laboratory has done some valuable work on methods of domestic heating, thermal insulation, and related physical problems But there has been no co-ordination between these diverse efforts , nor any institution wholly devoted to problems of the building industry

This anomalous state of affairs is now to be abolished with the establishment of a Building Research Bureau, which is being sponsored by a joint committee of the New Zealand Master Builders' Federation and the New Zealand Institute of Architects Dr Lyndon Bastings has been appointed the first director It is intended initially to set up a library and an information service , but as funds allow, it is hoped that laboratories and other practical facilities will follow in due course The address of the new Bureau is Construction House, 66 Murphy Street, Wellington, N 1, New Zealand

Postgraduate Courses at the Imperial College of Science and Technology, London

ADVANCED postgraduate study has long been a special feature of the work of the Imperial College of Science and Technology, University of London As new types of technology emerge—of which nuclear power and soil mechanics are notable recent examples —they open up possibilities of study which must remain outside the scope of any course for a first degree but which are properly within the field of university teaching The postgraduate courses at the College have been greatly increased in number in recent years to meet the wide range of technological development Postgraduate courses provide the opportunity for students, including many who have already spent a year or more in industry, to further their knowledge in a particular specialized field, and at the same time to learn from experts their experience of the application of this knowledge in industry. Details of the courses are set out in an impressive handbook published by the College (Postgraduate Courses, 1959–60 Pp xii+111 London Imperial College of Science and Technology, 1959) , the list should give considerable satisfaction to all who are concerned with Britain's place in the world of technology Many of these courses have been accepted by the Department of Scientific and Industrial Research as suitable for the tenure of advanced course studentships Grants for the courses related to agricultural science are awarded by the Ministry of Agriculture, Fisheries and Food The courses are assisted by industry , in particular, a number of firms support the work of the advisory committees in concrete technology and technical optics and provide bursaries for the respective courses

Sandwich Course in Executive Development

THE Department of Commerce and Management of Sheffield College of Technology is to provide a sandwich course in executive development commencing in November 1959 The purpose is to provide for the young manager and potential manager a fully integrated plan of executive development, by bringing together in one scheme both education for management within the College and general and vocational managerial experience in his working environment Full-time attendance at the College will be required for approximately fifteen weeks during each year of the course, and will be spread over a period of two academic years Only students already engaged in industry, and individually sponsored by their employers will be accepted into the course Further information can be obtained from the Head of the Department of Commerce and Management, 1, Melbourne Avenue, Sheffield, 10

Developmental Biology

THE first number has recently appeared of a new journal, *Developmental Biology*, published by the Academic Press, and produced by an editorial board consisting of Prof J Brachet, Prof E Hadorn, Dr P Weiss with Prof M V Edds of the Department of Biology, Brown University, as managing editor (*Developmental Biology*, Vol 1, No 1, April 1959 Pp x+124 Volume 1 (6 issues) 14 dollars New York and London Academic Press, Inc, 1959) The manuscripts in English should be sent to *Developmental Biology*, Department of Biology, Brown University, Providence, Rhode Island, U S A those in French to J Brachet, Laboratory of Animal Morphology, University of Brussels, Brussels, Belgium, and those in German to E Hadorn, University of Zurich, Switzerland Many of the classical divisions of biology no longer correspond to the way in which research is organized and thought develops in biology to-day The formation of this journal is an attempt to produce some degree of rationalization by bringing together studies of all aspects of development and growth This is well exemplified by the contents of the first number, which contains articles dealing with the chick embryo, with *Drosophila* larvæ, with the ribonucleic acid involved in differentiation of a fern and with the function of SH groups in morphogenesis In the editorial to the first number the editors say that they are prepared to accept articles written from a wide variety of points of view, for example, analytical or descriptive, technical or theoretical, using either a molecular approach and/or an organismal approach Micro-organisms plants and animals are all equally regarded as relevant to the problems of developmental biology

Native Life in Angola

THE Portuguese Companhia de Diamantes de Angola is noted for the interest it takes in archæology and the native cultures of the region in which it operates Business firms are not usually directly concerned with interests of a cultural nature outside their own money-making projects, and this makes it all the more remarkable that the Angola Diamond Mining Co has published already a large number of splendid volumes, full of illustrations which deal with many aspects of the past and present history of the country A recent volume (Companhia de Diamantes de Angola (Diamang) Servicos Culturais Dundo–Lunda–Angola Museu do Dundo Publicacões Culturais No 37 Flagrantes da Vida na Lunda Introducão de José Osório de Oliveira Pp 192 (Lisboa Companhia de Diamantes de Angola 1958)) is a superb publication of large format containing no less than 148 full-page illustrations of the countryside and its inhabitants. We can see basket-makers at work, fishing scenes, a moment in a divination ceremony, a Lunda chief with his robes and ceremonial insignia, etc The first 44 pages are devoted to an introduction by Dr José Osório de Oliveira, there being Portuguese, French, and English versions An account of some of the cultural activities of the company is given and also of the country and its people On the last page the author writes. "The honour attributed to the leaders of 'Diamang' in having anticipated in Africa that which the experts convoked by UNESCO counselled is nothing more than justice, for one cannot fail to look upon the company as the keystone of local native life" This is true, and furthermore, both archæologists and anthropologists all over the world have reason to thank the Company for the Dundo Museum and many other contributions to learning

Summer Tanager

FOLLOWING a series of depressions and strong westerly winds, an unusual bird was observed on Bardsey Island on September 11, 1958 It was somewhat smaller than a song thrush, olive green above and deep yellow below, with a heavy blunt bill and peculiarly short legs Subsequent observations suggested that the bird was a summer tanager, *Piranga rubra*, which had not previously been recorded in any European list, the few red feathers on the head and the back suggested that the specimen was a young male Details of the observation and of the highly successful work carried out at Bardsey Bird and Field Observatory during 1957 are described in the annual report of that Observatory for 1957, which can be obtained from W M Condry, Eglwysfach, Machynlleth, Montgomeryshire

Chromosome Numbers in *Solidago*

IN further studies of the genus *Solidago*, J R Beaudry and D L Chabot (*Canad J Bot*, 37, No 2, 1959) have observed the chromosome numbers in 25 taxa of the genus In all, the chromosome numbers of 42 taxa have now been published. The basic number of the genus is nine Thirty-three taxa are diploid ($2n = 18$), five are tetraploid ($2n = 36$), three are aggregate taxa containing both diploid and tetraploid cytodemes, and one is hexaploid ($2n = 54$) Polyploidy has thus contributed to the evolution of the genus *Solidago* but it seems that most of the species have differentiated gradually *S decemflora* DC of western North America differs from *S nemoralis* Ait of the same continent by morphological characters, its geographical distribution, and its chromosome number, the first taxon being tetraploid and the second diploid; the two are thus good species and not merely varieties of the same species *S rigida* is considered to be an aggregate, consisting of two entities which are distinguished not only by their morphology and geographical distribution but also by their chromosome numbers; the eastern one (*S rigida* L) is tetraploid, whereas the western one (*S parvirigida* Beaudry) is diploid. The bog and marsh goldenrods, *S Purshii* and *S uliginosa*, also possess different chromosome numbers, the first being diploid and the second tetraploid

Soil Fungi in the Belgian Congo

J MEYER has given a comprehensive account of soil and litter fungi in the Belgian Congo (region of Yangambi) (Publications de l'Institut National pour l'Étude Agronomique du Congo Belge Série Scientifique, No 75. "Moisissures du Sol et des Litières de la Région de Yangambi (Congo Belge)", par J Meyer Pp 211+4 planches Bruxelles: Institut National pour l'Étude Agronomique du Congo Belge, 1959 190 Belgian francs) In this work, the author has recorded his taxonomic observations on the very considerable number of fungi observed or isolated, leaving the questions of sociology, synecology, etc, to be dealt with later The generally accepted classification of soil fungi into native or cosmopolitan species, and exotic fungi (soil invaders), is followed, but the author notes that the exotic organisms require further sub-division into two groups, namely, preferent species (*espèces préférentes*), implying having precedence or priority, and exclusive species The nature of the vegetation, and the fruits, leaves and branches which fall from it to form the litter, carrying down air-borne organisms by which they have become infected, influences the nature of the exotic fungal flora So also do rhizosphere relationships Hence the author considers that the work of the soil mycologist must necessarily suffer limitations if it fails to take into account the nature of the vegetation and its litter, that is to say, properly envisaged, the phenomenon to be investigated is that of vegetation–litter–soil In this initial study, some 251 species are listed, described and many of them illustrated Of these, 191 came from the soil (13 Phycomycetes, 31 Ascomycetes, and 147 Deuteromycetes) and 60 were observed directly on debris The Hyphomycetes have been classified according to Hughes's system (1953)

Precambrian Geology of South-western Australia

The Precambrian geology of south-western Australia has recently been reviewed by A F Wilson (*J Roy Soc Western Australia*, 41, 57, 1958), who provides a new tectonic-geological map of a quarter of a million square miles of this region on a scale of 20 miles to the inch This is the first attempt to integrate all known trends of granites, gneisses, and 'greenstones', and on the map these and charnockitic rocks are distinguished for the first time The well-known north-north-westerly trend of the Goldfield areas is found to extend in a general way throughout much of the region The strike of the granites conforms to the regional strike of the metamorphic rocks, but magmatic emplacement is suggested locally Granitization contacts are also common, and filter-press differentiation phenomena are known Geochemical and petrographic features suggest that many gneisses are similar in composition to greywacke rocks, but that the granites would need to have been subject to some *K*-metasomatism to have been produced from such a source Charnockitic rocks are found over a very large area, and seem to have developed in at least four different ways, and in two main periods—one early and the other late Archæan It would appear from radioactive age determinations that the bulk of south-western Australia is of early Archæan age, and that a late Archæan period of metamorphism has affected parts of the south and south-east, and also possibly the western margin of the shield which is down-faulted beneath the Perth basin.

Perkin Centenary Trust Awards

The Perkin Centenary Fellowship has been awarded to Mr Brian Whitear, a research chemist in the laboratories of Messrs Ilford, Ltd Mr Whitear will work at the University of Southampton, under the supervision of Prof R C Cookson, on photochemical reactions of coloured substances Perkin Centenary Scholarships have been awarded to the following Mr Ronald R Cox (tenable at the University of Birmingham), Mr B T Lawton (tenable at the Royal Technical College, Salford), and to Mr D J Pearson (tenable at the Bradford Institute of Technology)

University News

Hull

The annual report, 1957–58, of the University of Hull notes the establishment of the grade of senior lectureship, to which eight lecturers have been promoted, and also another large deficit on the halls of residence Residence fees have been assessed to provide a surplus, and if costs do not rise appreciably an overall deficit should be avoided during the next three years The first stage of the new library building is expected to be completed in the summer of 1959 and a provisional building programme at an estimated capital cost of £949,000 has been approved by the University Grants Committee for the years 1960–63 including a new physics building, a hall of residence on the University site, an arts and social science building, and extensions to Ferens Hall The completed programme will cost nearly £2 million and will provide places in Hull for about half the 2,000 students expected in the University in the '60's The Senate's report includes brief notes on research work in progress, an account of the work of the Department of Adult Education and a list of publications during the year, arranged under departments

Announcements

H R H The Duke of Edinburgh has accepted an invitation to become the first Honorary Fellow of the Illuminating Engineering Society

Prof J H Mathewson, of the Institution of Transportation and Traffic Engineering, University of California, will give two lectures at the Road Research Laboratory, Langley Hall, Langley, Slough, Bucks, on "Experiments on Automobile Collisions" (September 9), and "A Simulator for Research on Driver Behaviour" (September 16) Both lectures will commence at 3 30 p m Tickets can be obtained (free) on application to the Director of Road Research, Road Research Laboratory, Harmondsworth, West Drayton, Middlesex

Sir James Denby Roberts has been appointed chairman of the Joint Committee of the Agricultural and Medical Research Councils and the Development Commission on Biological (Non-Medical) Problems of Nuclear Physics in succession to Lord Rothschild, who retired earlier this year This Committee was formed to sponsor and co-ordinate research on the effects of radioactive substances on plants and animals, and is responsible for the supervision of monitoring fall-out in foodstuffs and other biological materials Sir James is chairman of the Scottish Society for Research in Plant Breeding and is particularly interested in farming in the Highlands

It is announced that the Commonwealth Scientific and Industrial Research Organization (Australia) has formed a new Division of Mineral Chemistry, replacing the Minerals Utilization Section of the Organization's Chemical Research Laboratories The Division's research under the leadership of Mr R G Thomas will be concerned with the chemical transformation of minerals into a wide variety of useful products

A coloured wall-chart illustrating in section the Metro-Vickers Type *EM*6 electron-microscope has recently been produced primarily for the use of technical colleges and teaching institutions Supplies have been reserved for lecturers and science teachers and requests for copies should be addressed to the Publicity Department of Metropolitan-Vickers Electrical Co, Ltd, Manchester

INDUSTRIAL RESEARCH ASSOCIATIONS IN BRITAIN

"RESEARCH for Industry, 1958", which reports on work done by the industrial research associations in the Government scheme, this year adopts a new pattern which has much to commend it. It includes the report of the Industrial Grants Committee of the Council for Scientific and Industrial Research which comprises a review of grant policy during 1957–64 (see p. 211 of this issue), and a review of the achievements during the past five years of the ten research associations to which new or revised terms of grant were recommended during the year. Apart from brief notes on any outstanding features of the work of other research associations during the period, the bulk of the report comprises a list of existing associations, giving their officers, total income and publications during the year and a brief note on the scope of the present work of each association. There is also an assessment by Dr. D. T. A. Townend of the place of the research associations in the evolution of scientific endeavour, and a report entitled "New Ideas, New Products, New Processes" on how co-operation research serves the textile industries. In this report, which covers the work of several research associations, the point is made that one-fifth of an association's resources is only adequate for fundamental research if the total resources are big enough.

Of the research associations which received new or revised terms of grant during the year, stress is laid on the basic research into the composition of gelatin and glue, the structure of the gelatin molecule, the properties of solutions and gels and the conversion of collagen into gelatin being carried out by the British Gelatine and Glue Research Association; the economic value of the work of the British Hat and Allied Felt Makers' Research Association; the achievements of the British Hydromechanics Research Association in the design and utilization of pumps and in high-pressure hydraulic machinery and in hydraulic model testing. The Furniture Development Council has conducted a basic investigation into factors affecting the strength and rigidity of cabinet construction, developed test methods for furniture lacquers and worked on a new, economical material—wood chipboard. The Heating and Ventilating Research Council began its first major research project in 1956–57—an investigation of problems arising from the intermittent heating of buildings, with the view of ascertaining possible fuel savings by choosing in advance equipment and programme of the daily heating cycle in relation to the thermal characteristics of the building and installation. The Lace Research Association has carried out much work on new types of yarn and on problems arising in dyeing and dressing synthetic fibre materials, and is engaged in a basic study of the bobbin and carriage, which is the central feature of major types of lace machines.

Basic research carried out by the British Flour-Millers' Research Association includes a complete analysis of the amino-acid composition of flour and of the changes which occur when it is made into bread. The Research Association of British Rubber Manufacturers has extended its cover to plastics, notably polyvinyl chloride and polyethylene, and has been investigating the basic physical characteristics of rubber and plastics and the influence of service conditions such as temperature on these characteristics. An outstanding piece of chemical research increased knowledge of how traces of certain metals, notably copper and manganese, can cause premature deterioration of important classes of rubber products, especially rubber-proofed fabrics. The British Coke Research Association has developed instruments such as an isothermal bomb calorimeter for accurate determination of the calorific value of solid and liquid fuels and an electromagnetic semi-microbalance for use in fundamental studies relating to carbon.

AGRICULTURAL RESEARCH IN BRITAIN

A CORRESPONDENT, commenting in a Scottish farming paper on the Report of the Agricultural Research Council for 1957–58, complained that he could find no reference to research on grass tetany. Because of its current seriousness, he felt that some of the four million pounds that the Council administers should be allocated directly towards research into this problem. If he had read the report with deeper understanding he would have realized that such a criticism was not really justified. For example, at the Rowett Research Institute there are in progress fundamental studies on the physiology of rumen digestion with particular reference to young grass which is high in potash and nitrogen. The work is not labelled grass tetany or hypomagnesæmia, but it is in fact just the sort of work that will lead to a better understanding of the metabolic diseases of livestock which are still very largely unsolved. Agricultural research has long since passed from its old phase of an empirical approach to outstanding problems, and this is well illustrated by this report, for the main emphasis is on fundamental studies necessary for a better understanding of the vital mechanisms of plants and animals.

Another illustration of this approach is provided by the investigations, mainly at Rothamsted Experimental Station and at the University of Durham, into the biology of the potato root eelworm. Studies have been made of diffusate from potato roots which stimulates hatching of the cysts, and investigations are proceeding at several centres into the chemistry of this material, with the view of obtaining a means of causing hatching in the absence of the host plant.

A feature of the report is the very considerable emphasis which is given to the several aspects of poultry research, which for a number of years was something of a Cinderella so far as the Council was concerned. The industry, with an annual output of £200 millions, is second in importance in Britain to dairying, and it also is one of the most heavily subsidized. It is very important that the industry should be more efficient, and especially is this true in respect of disease control, for wastage is a very heavy source of loss To-day there are two poultry research institutes, one wholly and the other partly financed by the Council, while there is a considerable amount of poultry research being supported at other centres One pleasing aspect of the breeding work is the attention that is being given to methods which will be within the compass of the small breeder, who is in imminent danger of being squeezed out by the large organizations producing hybrid chicks

Possibly the most notable advance from the point of view of the farmer relates to the control of husk in cattle, which is caused by the lungworm, *Dictyocaulus viviparus* This work has been undertaken by the University of Glasgow Veterinary School and was started in 1952 The successful outcome of this work is that double vaccination, using doses of larvæ that have been partially inactivated by irradiation with X-rays, gives an effective field control of a disease which has been a serious source of loss to farmers The cost to the cattle industry has not been confined to deaths and loss of thrift, but has included also the cost of housing and hand-feeding susceptible animals in order to avoid infection Now that farmers have an effective control of the disease, it will be possible for them to put calves out to pasture and thereby considerably lower the cost of rearing X-irradiation opens up enormous possibilities in the control of other endo-parasitic infections, and further work is proceeding on this side

One final point about the Council's activities—though the greater part of its funds go to research institutes such as Rothamsted Experimental Station and the National Institute for Research in Dairying, the universities are by no means neglected Apart from a number of research units, there were ninety-four separate projects at sixteen universities which were receiving grants in March 1958 It seems that fears expressed a few years ago that the big institutes would monopolize research in agriculture, and the sciences basic to agriculture, are groundless, for it is obviously the Council's policy to encourage workers at the universities, who have, among their other duties, the task of training research workers to staff the institutes

SELF-REGULATION IN LIVING SYSTEMS

THE first Ottawa symposium on self-regulation in living systems, held in October 1958 (see *Nature*, 183, 730 , 1959), led to requests for a second meeting with particular emphasis on problems of stability in self-regulating systems This meeting was held at the National Research Council laboratories in Ottawa on March 11 As on the previous occasion, a very wide range of professions was represented, and the attempt was made to increase our understanding of the behaviour of living systems by analogy with known physical and mathematical techniques and concepts

The opening paper, outlining the nature of the problem, was by a physiologist, Dr A S V Burgen (McGill University, Montreal) Burgen emphasized that all physiological problems are multifactorial in character, and that in a real biological system it is impossible to isolate a single variable A real need exists for more adequate mathematical techniques to deal with such problems However, at present, simplifying assumptions are essential in order to reduce problems to manageable form Thus we may, for example, consider the blood circulatory system as made up of two pumps—namely, the right and left ventricles of the heart—connected in series with each other and with the blood vessels of the body The problem here is how the outputs of the two pumps are maintained equal to one another It is found that over a wide range of input pressures the output flow is proportional to this pressure, and in this way automatic regulation is achieved It appears that blood pressure is controlled by sensors acting via the base of the brain to cause dilation or contraction of capillaries in the circulatory system In these cases, and, for example, in the problem of maintenance of body temperature, the mechanisms by which the actual operating values are determined remain largely unknown at present It was also pointed out that there are definite time-cycles within the body for which at present no explanations have been given Following Burgen's paper there was considerable discussion as to whether the dependence on temperature of the rate of chemical processes might provide an adequate mechanism for the maintenance of an internal temperature standard

Dr A C Smith (Computing Centre, University of Ottawa) presented some analysis of the properties of idealized control systems, using the method of the Laplace transformation The analysis, however, was limited to strictly linear systems, and it was felt that the *non*-linear problem is in fact of great importance to physiologists and others The conclusion reached in the analysis was that optimum control conditions obtain when the control action depends upon both the variable under control and its time derivative This conclusion agreed with the general experimental observations of the physiologists present In the discussion the influence of time delay or phase of negative feedback on the stability of systems was of primary interest Physiological systems discussed in this connexion included problems of neurological instability and the recent work, reported in the literature, on the relation between stammering and delays in the reception of aural signals The galvanometer amplifier using a light beam and photocell to provide a high degree of negative feedback offers a simple mechanical system showing some of the important features If the time delay in the response of the cell is appreciable, the galvanometer amplifier system may 'build up' to a state of oscillatory instability It should be emphasized that the polarity of the feedback is still nominally negative , if the feedback is connected up in the opposite sense (positive feedback) then the galvanometer amplifier becomes entirely unstable, and obviously so !

An outline of some modes of operation of digital computers by Dr Bradford Dunham (Research Laboratory, International Business Machines, Poughkeepsie, New York) opened the way for analogies to be drawn with living systems In programming a computer a specific problem must be given a precise mathematical formulation and then translated into machine language Under these conditions we may say that the machine will either perform activities requiring no 'judgment', or it may be adapted to include activities requiring 'judgment' provided that the programme contains some means for evaluating consequences We can then go further and consider problems which are rather inexact, or poorly defined, with the condition that the answer(s) to the problem (which may be very difficult to find) must be easy to check or recognize as correct when arrived at In order to do this, the machine changes its own programme in some successive manner and at the same time evaluates the effect of these changes It certainly appears that this technique of 'machine search' can be regarded as a learning process (perhaps even more ?) in that the machine itself attempts to arrive at the correct way to tackle a problem

Dr F L McNaughton (Montreal Neurological Institute) made some remarks on stability in relation to the human system, pointing out first that we are still far from an adequate understanding of how the brain works Experiments in which people were isolated from their environment result in hallucinations in the experimental subject and some distortion of perception when the period of isolation is ended, a clear interdependence of nervous system and environment is indicated When this adjustment of man to his environment breaks down he shows the symptoms of disease Broadly speaking, it appears that only damage or disease in the general receptor or motor areas of the brain produce immediately identifiable external symptoms Considerable parts of other areas of the brain may be removed or quite drastic surgery carried out, with what appear to be only transient after-effects in many cases In discussion, the close analogy between the apparent organization of the human brain and the problem of 'machine search', mentioned above, was pointed out It has been found that in machine 'learning' of this type, the initial and final stages of the programme (which might perhaps be likened to receptor and motor areas) are critical in the solution of the problem, but otherwise many alternative programmes appear to be possible

Dr G Glinski (Department of Electrical Engineering, University of Ottawa) spoke on the general problem of stability and adaptability of multi-loop feedback control systems Systems of this type are much closer to living systems than the simpler control systems discussed earlier since a number of variables are involved in controlling a single output In addition, there may be feedback to one or more inputs and it is also possible to take into consideration some interaction between input variables

In the previous symposium, Dr A C Burton (University of Western Ontario) presented some demonstrations on the significance of visual perception The present symposium concluded with a short demonstration by Dr Burton of interaction between visual inputs This followed an experiment first performed by Mach in which an interaction between neighbouring receptors in the eye leading to a sharpening of the contrast between light and dark regions is shown quite dramatically by the apparent presence of intensified dark and light bands in the penumbra region of a straight edge when projected on to a lantern screen

Following the meeting, a panel discussion took place on the Canadian Broadcasting Corporation system under the chairmanship of Sir Robert Watson-Watt, in which Drs Burgen, Dunham and MacDonald took part During this spontaneous discussion the significance of 'learning' by machines was explored further It is probable that a further symposium will be held—perhaps this time in Montreal

D K C MACDONALD
DOUGLAS L MARTIN

THERMONUCLEAR PROCESSES

A CONVENTION on "Thermonuclear Processes" was held in the Great Hall of the Institution of Civil Engineers on April 29–30 The convention was organized by the Institution of Electrical Engineers in conjunction with the British Nuclear Energy Conference A total of twenty-two papers were read, half of which were concerned exclusively with the engineering problems arising out of research into controlled thermonuclear reactions The remaining papers were largely re-statements of results given at the Geneva Conference on the Peaceful Uses of Atomic Energy last year, albeit presented in a form more suitable for a predominantly engineering audience However, some new results were given, particularly in the papers submitted by the United States and the U S S R

The mechanism of energy loss remains the outstanding question in connexion with the toroidal stabilized pinch or *Zeta*-type discharge At the Geneva Conference, Dr S A Colgate of the University of California claimed that the entire energy loss during the first 7–8 μsec of the discharge life-time in his small torus was due to runaway electrons with an energy of about 2 keV striking the walls Later, Drs Hughes and Kaufmann of Associated Electrical Industries, Ltd, Aldermaston, published results obtained with the *Sceptre* apparatus showing that impurity ions were drifting around the torus with the unexpectedly high velocity of 10^6 cm/sec The angular momentum of the deuterium plasma deduced from these measurements was in agreement with the notion of runaway electrons as the chief source of loss This happy unanimity was destroyed by the release of two further results during questions at the Convention First, a search had been made on *Zeta* for the Doppler shift in impurity spectra indicating drift motion and none had been found Secondly, the group at Los Alamos under Dr J A Phillips working with *Perhapsatron S*4 had some evidence to show that the whole of the energy loss from their torus was due to radiation in the vacuum ultra-violet region Clearly more work will have to be done before the problem is finally resolved

Mr G B F Niblett of the Atomic Weapons Research Establishment, Aldermaston, described some new experiments on the rapid compression of plasma In this work a fast-rising axial magnetic field is created inside a linear discharge tube by means of a long single-turn copper coil coupled to a condenser bank The resulting ring discharge ionizes the gas and is rapidly collapsed by the rising magnetic pressure The heating principle is the same as that of the fast linear pinch first reported by Kurchatov at Harwell in 1956, but the changed geometry avoids electrode effects and is expected to be hydromagnetically more stable A ringing discharge with a frequency of about 200 kc /s was produced in a $1\frac{1}{2}$-in bore tube A rotating-mirror photograph of the discharge in nitrogen showed successive contractions of the discharge corresponding to the oscillations of the coil current In other measurements, the radial oscillation of the hollow cylindrical shell of plasma when confined between two magnetic fields was observed It was suggested that these oscillations might be used to heat the plasma

A paper presented by Mr J D Jukes of the Atomic Energy Research Establishment, Harwell, analysed a system for extracting electrical energy directly from any fusion reactor which uses the principle of magnetic confinement To extract the energy, the plasma is taken through a compression cycle by varying the confining magnetic field During the compressed state, energy accumulates in the plasma due to the burning of the nuclear fuel When expanded the plasma temperature is low so that fusion reactions occur infrequently and the plasma cools, losing energy by bremsstrahlung radiation In this way, waste heat is removed from the plasma and a closed Carnot cycle can be achieved Since the neutrons produced in the fusion reactions are unaffected by the magnetic field, only the energy released in charged particles can be extracted in this way Mr Jukes concluded that it should be possible to withdraw about one-third of the available energy from proposed fusion devices directly as electrical energy

Dr C M van Atta of the University of California Radiation Laboratory presented a survey of the very large American programme in this field which costs 40 million dollars a year and employs three hundred professional staff A new experiment demonstrating the propagation of torsional Alfvén waves through plasma was described To produce the plasma a linear discharge carrying a current of 20 k amp in an axial magnetic field of 10 kilogauss is used The waves are generated by applying an alternating radial electric field between one of the electrodes and the conducting wall of the tube The measured velocity of propagation increases linearly with the axial magnetic field strength and is in close agreement with theory if the ion density is assumed to correspond to all the gas initially in the tube being ionized This work is being done by Dr J Wilcox at the Radiation Laboratory, Berkeley Among other experiments reported in this paper were hydrodynamic stability studies by Dr S A Colgate using high current pulses through sodium, and similar studies by Dr H P Furth using plasma and a variety of magnetic field configurations

An important consideration in the magnetic-mirror method of confinement is the accuracy of the assumption that the magnetic moment of a spiralling charged particle is a constant The principle of mirror confinement is based on this adiabatic invariance, and since a confined particle may undergo many millions of reflexions from the mirrors during its containment, the accuracy required is of a high order In experiments by Dr E Lauer of Berkeley, positions with energies of the order 1 MeV resulting from the β-decay of radioactive neon were shown to be contained between magnetic mirrors for 10^8 reflexions The distance between the mirrors was 1 m and the Larmor radius of the electrons 6 cm

Dr I N Golovin of the Institute of Atomic Energy, Moscow, gave an account of research into magnetic-mirror systems in the Soviet Union He described an experiment on the adiabatic invariance of the magnetic moment similar in principle to that reported by Dr van Atta In this case electrons from the radioactive decay of tritium were used and confinement for up to 10^7 reflexions had been demonstrated Work had also been done to find the effect of azimuthal asymmetries in the magnetic field on the number of reflexions It was found that until the azimuthal variations in the magnetic field strength exceeded about 10 per cent there was no effect on this containment The remainder of Dr Golovin's paper was devoted to a discussion of the work on *Ogra*, the large Russian mirror machine He stated that *Ogra* was built to study plasma instabilities and was designed to produce a hot plasma with a density of 10^{12} ions/cm ^{3} if no instabilities were encountered The principle of injection in this machine is that of dissociation of the input beam of 200-keV molecular ions through collisions with the residual neutral gas in the volume By balancing the favourable process of dissociation against the unfavourable one of charge exchange, it can be shown that a dense plasma will only be formed if the input beam current exceeds a certain value, the so-called burn-out current The burn-out current for *Ogra* was calculated assuming that the background neutral gas density was determined by the ionization of neutral gas by fast ions and by the release of neutral gas from the walls through the impact of fast particles A figure of the order 200 m amp was obtained for the formation of a hydrogen plasma Another assumption in the calculation was that the path-length of an injected molecular ion moving in the magnetic field and failing to make a collision should be not less than 10^5 cm before it returns to the injector This length depends critically on the magnetic field configuration and the ion gun alignment, and one of the first tasks with the machine will be to optimize these A very low initial pressure is also required and to date the lowest value achieved has been $\sim 3 \times 10^{-8}$ mm mercury In view of the size of the vacuum chamber, 1 5 m bore and 20 m long, this represents a considerable technical achievement The present ion-source gives 150 m amp of molecular ions at 100 keV Up to the moment only a 30-m amp beam of ions has been injected into the machine and the burn-out condition has not been achieved Impressive photographs were shown of the beam spiralling in the magnetic field

During question time, Dr K W Allen of the Atomic Weapons Research Establishment, Aldermaston, raised the subject of the order of magnitude difference in the relevant charge exchange cross-sections as measured by Fedorenko in the U S S R and by Barnett in the United States Replying, both Dr van Atta and Dr Golovin declared their faith in the measurements carried out in their respective countries, but Dr van Atta hoped that the work would soon be repeated in a third and preferably neutral country Other points raised during discussion periods concerned the importance of the spectral region 10 A – 400 A for plasma measurements, the power lost by synchrotron radiation from the electrons in a magnetically confined plasma and the need for more work on surface bombardment effects

Finally, Sir George Thomson called for more refined experiments, with purer plasma and more homogeneous magnetic fields He concluded by declaring his faith in the ultimate solution of the problem of obtaining economic power from fusion reactions

R BICKERTON

BRITISH NON-FERROUS METALS RESEARCH ASSOCIATION

NEW RESEARCH LABORATORIES

ON May 13 Sir Alexander Fleck, chairman of Imperial Chemical Industries, Ltd., opened a new laboratory block for the British Non-Ferrous Metals Research Association at Euston Street in London. The laboratories have gradually been extending on this site since 1930 and now contain about 53,000 sq. ft. of floor space and house a staff of about 180. They serve the needs for co-operative research of practically all branches of the non-ferrous metals industry, and the 40–50 research projects in progress cover the production, properties and uses of the commoner non-ferrous metals, certain aspects of the metallurgy of the metals concerned with nuclear energy, and metal finishing.

The new laboratory was made possible by the generous response to a building fund on the part of the Association's membership of more than 600 firms and of the Department of Scientific and Industrial Research, which has treated contributions as grant earning. The main features of the new block are a much-enlarged foundry, new corrosion and physics laboratories and a new electroplating shop. Alterations to existing buildings have enabled a new creep testing laboratory to be built which will allow the capacity to be doubled to more than 100 units, the rehousing of many different types of fatigue testing machines in one room, and the provision of more space for the General Metallurgy Section. This, among other things, gives the Section more room for vacuum apparatus for the determination of gases in metals.

In the foundry, moulds are now made in one well-equipped bay and poured in an adjacent melting and casting shop. The melting equipment consists of five gas-fired lift-out crucible furnaces, a gas-fired bale-out furnace for research into die-casting problems, a 600-lb. low-frequency induction furnace for studying the performance of refractory linings, and also an electric resistance furnace and a high-frequency furnace each capable of melting charges of up to 20 lb. of copper or nickel alloys in vacuum or special atmospheres.

From the inception of the laboratories the value of physical methods of analysis has been realized and the Association's work in developing spectrographic analysis of metals to its present state of efficiency is well known. Recently, the X-ray fluorescence method of analysis has aroused considerable interest and it appears extremely promising for analysing the major constituents in alloys and for the analysis of ores and slags. Its potentialities are being studied, using a spectrometer designed by the Physics Section and built in the Association's workshops. In the Chemistry Section emphasis is on the physico-chemical methods of analysis, including polarography, spectrophotometry and the use of the flame spectrophotometer.

The Physics Section has two X-ray diffraction sets and a variety of special-purpose cameras for crystal orientation studies, the identification of phases in compounds and other tasks. An electron diffraction camera is available for studying oxide and other thin films on metal surfaces.

Instrumentation for automatic inspection and process control is becoming increasingly important in the metal industry, and several studies are being made of problems in this field. They include the use of eddy currents for rapid inspection of tubes and rods for flaws, an investigation into emissivity variations of hot metal surfaces which affect the performance of radiation pyrometers, and the development of a novel thermo-electric gauge for measuring, non-destructively, the thickness of electro-deposits.

Research on electroplating and allied metal-finishing processes is now housed in a large new laboratory equipped both for fundamental work and for plating on a semi-industrial scale in pilot plating lines. Equipment is available for measuring the stresses during plating, for measuring cathode potentials and throwing power, and for assessing the ductility and adhesion of coatings. Exposure tests on plated specimens are carried out on the roof of the laboratories, but much work has been done on accelerated corrosion tests, including one in which the parts are exposed to a humid atmosphere containing traces of sulphur dioxide which simulates in a few hours the effects of exposing the parts to a city atmosphere for several months.

Many modern plating solutions contain organic additions which affect the smoothness, brightness and mechanical properties of the coatings in a beneficial way. Exactly how these organic agents do this is not known, and typical addition agents prepared with tracers, such as carbon-14 and sulphur-35, are being used to study the mechanism of the process.

In the Corrosion Section one laboratory is employed solely for sea-water corrosion studies, the current work being concerned mainly with the attack on heat-exchanger tubes handling heavily polluted estuarine waters in power stations, oil refineries and in ships. Some of these tests are at controlled potentials to simulate the effects of applied cathodic protection. The influence of marine atmospheres is assessed by exposure at a site on Hayling Island and the laboratory roof site is used mainly for inland tests. Stress corrosion tests are carried out at both these sites and there is also a special high-humidity room for this purpose in the corrosion laboratory.

One of the main uses of non-ferrous metals is the handling of supply waters, and the effect of water composition on the resistance to corrosion of various metals is being studied at field stations and also in the laboratories using synthesized waters.

The General Metallurgy Section, besides carrying out the usual metallographic work, heat treatment and constitutional studies, contains a metal-working shop with a 12-in. rolling mill, a 500-ton press for extrusion and forging, a small forging hammer and a drawbench. This section of the laboratories is also working on the development of titanium, zirconium and thorium alloys and has argon-arc melting equipment appropriate for this type of work. Special apparatus which uses an atmosphere of argon for carrying out long-term creep tests on these reactive metals is housed in the new creep laboratory.

HIGHER EDUCATION IN EAST AFRICA

IN 1954, a delegation, headed by Dr. (now Sir) Eric Ashby, was appointed to assist in planning the development of Makerere College, Uganda. In addition to indicating the general scope of the development which it thought appropriate, the delegation also made reference to the broad problem of developing higher education in East Africa as a whole. As a result, a working party, under the chairmanship of Sir Alexander Carr-Saunders, visited East Africa in July 1955, to review in greater detail the requirements of higher education. Its findings were published in a White Paper[1], in which the Governments of Kenya, Tanganyika, Uganda and Zanzibar fully accepted the desirability of further university college development, within the scope of a single University of East Africa.

A second working party, under the leadership of Dr. J. F. Lockwood, visited East Africa in July 1958 to examine proposals for the creation of new institutions of higher education, in particular within the framework of a University of East Africa.

Its report[2], recently published, contains four main recommendations, which are being considered by the East African Governments: (1) By re-organization and extension, the Royal Technical College of East Africa, in Nairobi, should, without delay, become a university college of a new type, in which academic and professional courses of equal standing would have their place with Faculties of Science, Arts, Engineering and Special Professional Studies. (2) That plans should be formed for the establishment of an inter-territorial university college in Tanganyika at Morogoro, to be opened in 1965–66, or as soon thereafter as possible. (3) That a university of East Africa should be created by 1966 and that the university colleges then existing, and any which may be founded thereafter, should be associated as constituent colleges of the university. (4) Since the carrying out of these recommendations will guarantee adequate provision for higher technological and professional training for some years ahead, no additional institutions offering facilities for these kinds of training should at present be contemplated.

If these recommendations are accepted the new University of East Africa would have as its constituent colleges, Makerere College, the Royal College of East Africa (the reorganized Royal Technical College) and the new university college in Tanganyika. The report adds: "The inter-racial character of the colleges we take for granted as an indispensable element in their fully liberal nature and outlook". That they should also be wholly inter-territorial was likely for many years to be a vital necessity in terms both of academic need and of finance.

It is suggested that since the college in Nairobi would begin its career as a university college under the same system which now applies to Makerere College, students of the reconstructed college would work for degrees of the University of London, under a scheme of special relationship. The University of East Africa, following its foundation, would grant its own degrees, for which students of all the colleges would read. Since the university college in Tanganyika would probably not begin its teaching until after 1966, students of this college would, at the outset, read for degrees of the newly established university.

Though realizing that its proposals are modest, the working party stresses that the cost, in terms both of capital and recurrent expenditure, will be high, and points out that the several Governments will be unlikely to be able to meet capital expenditure from their own joint resources. "The compulsion of their present circumstances will thus force them to lean heavily on expectations of generous grants from Colonial Development and Welfare funds."

The report concludes with the hope that financial help will be forthcoming, for the individual colleges, from non-official sources, and pays tribute to generous gifts, which the Gandhi Memorial Academy Society has made to the Royal Technical College.

GLOEOSPORIUM IN APPLE STEM WOUNDS

TWO contributions on *Gloeosporium* in apple stem wounds have recently appeared (*J. Hort. Sci.*, 32, No. 2, 1959). R. O. Sharples has reported on an investigation of the response of apple stems to wound infections by the fungus *Gloeosporium perennans*. In anatomical studies relating to the establishment of infections on apple branches he has shown that the defensive mechanism of the host includes the production of suberized barriers by bark phellogens and the blocking of xylem vessels by gum deposition. These responses follow wounding, whether or not the wounds are inoculated with *G. perennans*, but the presence of the fungus delays the response. Accordingly the size and form of lesion induced by inoculation are largely determined by the effect of the fungus in postponing the normal wound healing process. This effect, and consequently penetration by the pathogen, is greatest during the period of host dormancy. Invasion occurs most rapidly through the sieve-tubes and the vessels and fibres of the outer xylem; the longitudinal intercellular spread of hyphæ through the cortex is slower.

Intracellular infection of the pith and medullary ray cells occurs in pruning-wound infections. When the progress of the infection is arrested, the phellogen and cambium lay down barriers of callus tissue consisting of parenchymatous outer cells surrounding a core of wound wood. After the lesion has been thus isolated, the fungus persists as a saprophyte and eventually forms acervuli on the exposed dead host tissue. A limited spread of infection past the suberized barriers occasionally appears to take place by way of the fibre bundles of the inner cortex

On the same topic, A T K Cooke has observed that *Gloeosporium* inoculations of pruning wounds on apple shoots are unlike branch wounds in that the cut tips of shoots are more or less susceptible to infection throughout the year, and that, although the extent of the infection is subject to the same host reactions as in lateral branch cankers, the normal healing process may be affected by seasonal conditions This emerged in a comparison of the behaviour of infected pruning cuts made on shoots at comparable times in successive years Sporulation on infected shoots was found to be greater in November than in March infections, beginning in both instances after one month Infections initiated during July first spored in December and produced very few conidia Like the branch infections studied during 1953–54, the shoot cankers yielded considerable numbers of conidia in the warm, wet months of December 1956–February 1957 The peak spore collection from the shoot cankers was in the June and July following inoculation, this being also a peak period for sporulation on the branch cankers

AIR SURVEYS AND THE SOCIAL SCIENTIST

By LEO SILBERMAN
University of Chicago

CO-OPERATION between the air survey team on one hand, and economists and social surveyors on the other, is likely to be greatly extended in the near future During the War photo-interpreters had to get along without systematic ground checks, and the relative rarity of combined studies of area sample surveys using questionnaires and air photographic coverage must be ascribed to a legacy from war-time

The advantages of combined operations are distributed equally between photogrammetrist and social student To the uses already made of air photography, the insights of the social scientists capable of interpolating more social and economic information from the records add further facts to those already known To the questionnaire survey the air photograph gives a much greater generality The samples can be extrapolated by multiplying the data for each typical unit by the total of this stratum found on the photographs This will provide an up-to-date sampling frame which in under-developed countries (though not only there) is usually lacking[1] By defining unambiguously the strata of which a regional population is composed, facilitating greater control, and allowing the ground surveyor to dispense with a large, often ill-educated and sketchily supervised staff, a better and speedier report can be furnished , this is often of great 'political' importance to the client The time factor is sometimes crucial

Photogrammetrist and sociogrammetrist in such a combined survey make their decisions together on the most practical scale of photography , the size of the ground sample that will give confidence in the statistical estimates , and the planning uses to which the results can be put Quantitative information is only part of the expected findings attention is often focused on the use made of space and the configuration of a neighbourhood However, social statistics will always cover a wide field, ranging from the count of slum properties to evidence of the spread of sleeping sickness

Air censuses taken of nomads in Palestine in the days of the British mandate and the censuses of Liberia and of Columbia both taken from the air are quantitative assessments of this kind Land-use studies in Malaya, making good use of the expensive photographs taken during the anti-terrorist campaigns and supplemented by family budget studies in that country, can be mapped so that hypotheses can be tested with the use of overlays A real property inventory is essential to a sociogrammetric survey but the use of such a survey in national and regional income investigations and capital growth and change studies is still to be fully appreciated

Regional comparisons are particularly important where there are jealousies between areas, and each claims self (that is, locally based) government, as in a number of West African countries, irrespective of whether it is economically feasible By giving the discussion some underpinning of fact the scales might conceivably be tipped towards a rational economic solution By comparisons between cognate regions we can appraise to what extent, with like endowments, policy or location has made labour and capital more productive Is it a nearby market, or education, or a longer period of peace that explains differential incomes of similar regions ? The analyst will not only wish to discover, as in the Gambia study of the Directorate of Oversea Geological Surveys, whether more rice is grown (a matter of political importance and controversy) but also why more rice is grown The term 'survey' implies study before planning A country like Ceylon taking a measure of its real resources, a project of the Colombo Plan, will also need to find out about its man-power, both quantitatively and, by the style of houses and state of agriculture, qualitatively[2] The Sudan not only wants to know where irrigation is technically feasible but also where there are Sudanese willing to take advantage of the arable land The country cannot absorb a limitless influx of foreigners from the west and north without creating a security problem

Once a clear picture emerges how an area works, the siting of a technical college or a new village becomes clear In built-up areas of rapid expansion public utility companies will want to know where and how the towns are spreading, so that offices can be strategically located, space reserved, and telephone lines not be intersected by other services above and below ground[3] The ground survey establishes to what extent houses are being subdivided and branch or independent line subscribers being added The state of the yards and many other things will tell us whether the area is improving or deteriorating In each area contrary influences are at work, each seeking dominance, as they spread from the various centres, and the racial strife of so many cities shows what bad neighbours peoples of different antecedents and standards of living make[4]

'Ecological statistics' can give in figures the area 'profiles'[5], for air photographs do not speak to everyone equally eloquently, just as maps and tables are permanent mysteries to some, unable to learn the conventions of each idiom or keep standard comparisons in their heads The aggregation of many individual values into composite, ecological statistics offers no problem to modern computing devices, which also are capable of mapping electronically information fed into them by some scanning apparatus in an aeroplane

Airborne radar, duplicated perhaps with magnetometers and gravitometers, adds to the sensitivity and completeness of the record Not only images but also radio waves, power points and carbon dioxide can be 'photographed' Infra-red photography picks up besides the aeroplane on the airfield the heat of the runway and thus the number of planes recently started The emphasis in modern photogrammetry has thus shifted from the static physical condition to the recordable human transactions

In brief, there are three chief ways in which such a survey can be used

(1) To supply general social and economic statistics such as the presence and growth of industry, agriculture, house building, road improvements, conservation and productivity, cross-checked with ground social surveys and nationally or regionally collected annual or census statistics

(2) The planning of policy and of improvements and services is based on these surveys A deft handling of photographic material should be combined with opinion studies and other studies on the ground, such as traffic and migration counts done by mechanical or human agents

(3) The evaluation of policy, that is, the effectiveness of any constructive activity This will probably be done increasingly as part of ordinary photogrammetric work with the help of someone competent in statistics and sociology and with a knowledge of the particular part of the world that is to be studied At a later stage, perhaps, when many different studies have been accumulated and compared, the skilled social interpreter may also be able to make useful deductions from a study of the photographs unaided by ground studies

EMISSION OF RELATIVELY HIGH-ENERGY IONS FROM LOW-VOLTAGE ARCS

By E. R. HARRISON

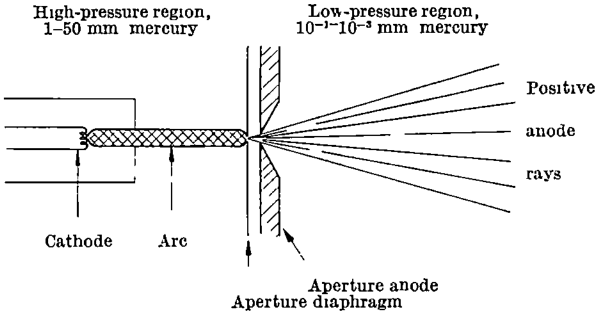
Atomic Energy Research Establishment, Harwell, Berks

SOME interesting effects have been observed with low-voltage arcs for which so far no completely satisfactory explanations have been found The principal effect observed is the emission of luminous rays consisting of ions of the cathode material at energies much greater than the total potential difference across the arc

In the experiments described below, the arc is formed between a tungsten, molybdenum or tantalum filament, which is separately heated, and a nickel anode at a distance of about 5 cm , and is maintained in a rare gas, usually argon, at a pressure of 1–50 mm mercury The applied potential difference is 40–80 V and the current is 200–500 m amp The arc is thermally constricted or 'pinched' to a diameter of approximately 5 mm In arcs of this kind[1] the electrons, ions and gas molecules are in an approximate thermal equilibrium at a temperature generally of the order of 10^4 °C The ionization potentials of tungsten, molybdenum and tantalum are lower than the excitation potentials of the rare gases and in the present experiments the arcs therefore tend to consist of ions formed from metal volatilized from the cathode[2] Spectroscopic analysis of the arc reveals strong W II and W I (Mo II and Mo I) lines but only a few faint argon lines

The first effect observed is that tungsten is deposited at the point where the arc makes contact with a cool nickel anode This deposition occurs even when the anode is screened from any material evaporated directly from the hot cathode The rate of deposition on the anode, as determined by activation analyses, is typically 3×10^{-6} gm /sec $^{-1}$ amp $^{-1}$, equivalent to a tungsten ion current of 1 5 m amp in an arc of 1 amp It appears that in hot cathode – cool anode arcs of this type there is an efficient mechanism for transporting positive ions from the cathode to the anode against the electric field It is evident that such a transport mechanism is required if the ions in the arc are formed originally from volatilized cathode material in the immediate vicinity of the cathode

A second effect is observed when the arc is constricted by a small aperture of ½–1 mm diameter in a nickel diaphragm placed between the cathode and anode, as shown in Fig 1 The cathode is now about 5 cm from the aperture diaphragm, and the anode is about 10–20 cm , or preferentially, the anode has a coaxial aperture of 2–3 mm diameter and is spaced about 5 mm from the first aperture, as is shown in Fig 1 On the anode side of the apparatus the pressure is maintained within the range of 10^{-1} to 10^{-3} mm mercury As a result of the constriction, impressive luminous white rays are observed projecting from the centre of the small aperture into the low-pressure region Occasionally, the rays form a uniform diverging beam, as in Fig 2, but more often



High-pressure region, 1–50 mm mercury
Low-pressure region, 10^{-1}–10^{-3} mm mercury
Positive anode rays
Cathode
Arc
Aperture anode
Aperture diaphragm

Fig 1 Apparatus for producing a constricted arc which ejects energetic positive ions through the aperture anode

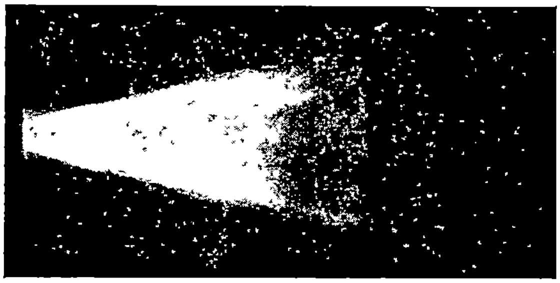


Fig 2 Positive tungsten ion rays of approximately 450 eV accelerated by an argon arc of 250 m amp and 80 V

the beam is divided into several individual rays of small diameter which flicker and move in synchronism with the instability motion of the arc Spectroscopic analysis of the deposit formed by the rays incident on a receiving target shows that the rays consist of tungsten atoms On changing the cathode material to molybdenum, the deposit formed by the rays is found to consist only of molybdenum, but the luminosity of the rays is unaltered and their colour only very slightly affected

Electrostatic and magnetic deflexion experiments establish the surprising fact that the rays are positively charged and have energies greater than the potential difference across the arc The accelerated ions are reasonably monoenergetic and have an energy in the range 100–750 eV , depending on the conditions of the arc With an aperture reduced to ½ mm diameter and a pressure of 80 mm mercury in the arc, tungsten ion rays with energies greater than 1,000 eV have been observed with a potential difference of only 60 V across an arc of 500 m amp Rays may also be observed when the pressure is as low as 1 mm mercury , in this case the arc develops only in a limited region adjacent to the aperture in a form reminiscent of a 'ball of fire'[3] The rays are not so easy to produce when the supporting gas is either helium or neon, possibly because the arc currents in these experiments are limited to relatively small values With krypton and xenon the rays are produced as readily as in the case of argon

Difficulty is encountered when attempts are made to measure electrically the current in the tungsten ion rays, not only because of secondary electrons but also because there is apparently an electron flux which is not easily eliminated Activation analyses of deposits formed by the rays incident on a target show that in a typical case there is a total flux of 0 4 × 10^{-6} gm /sec $^{-1}$ amp $^{-1}$ equivalent to 0 2 m amp in an arc of 1 amp This is consistent with the fact that a large fraction of the tungsten migrating towards the anode is deposited around the aperture More intense fluxes, up to 1 m amp per ampere of arc current, can be achieved by applying an alternating potential difference of 20–50 V between the cathode and an enclosing cylindrical electrode The flux and luminous intensities do not appear to be critically dependent upon the frequency in the range 10^4 to 10^7 c /s , and it is possible that the increase in intensity is due to the enhanced fluctuation movements induced in the arc

Potential fluctuations of up to 20 V. of the electrodes and movable probes have frequencies of 10^4–10^5 c /s. with a wide spectrum of 'hash' superimposed The fluctuations in luminosity of the rays as detected by a photomultiplier are similar to those of the arc and reveal frequencies in the same range as the potential variations The emission spectrum of the rays is predominantly W II, or in the case of a molybdenum cathode, Mo II

A third effect observed is that the rays frequently show a pronounced variation in intensity of luminosity along their length Thus, if the rays are projected into a region of low pressure of 10^{-3} mm mercury, in a typical case all rays are bright for the first 2 5 cm , the luminosity then becomes faint for about 0 5 cm , and then abruptly increases in intensity and thereafter diminishes slowly up to distances as great as 30 cm

A completely satisfactory explanation has not been found for all the effects described The luminosity of the rays is most probably due to charge exchange between the tungsten (molybdenum or tantalum) ions and the supporting gas , the abrupt variations in the luminosity, however, are not understood The mechanism responsible for producing the positive anode rays is most probably associated in some way with the transport of ions in the arc from the cathode to the anode The oscillatory or 'hashy' nature of the arc may be an essential self-sustaining feature[4] Thus, sound waves will be propagated with a phase velocity of $(\gamma kT/m)^{1/2}$, where m is the mass of the atoms of the supporting gas, and one possibility is that the electric fields produced by the separation of the electrons and ions are sufficiently large to cause a fraction of the ions to move with a drift velocity of approximately $(e\lambda E \sin\varphi/m)^{1/2}$ in phase with the sound waves, where λ is their mean free path, E is the oscillatory electric field, and φ is the phase angle Experiments designed to detect the propagation of signals along the arc at the phase velocity of sound have not been entirely successful, and the evidence is meagre and unconvincing Possibly the arc is in a turbulent state, and generates and propagates sound waves only over small distances

If disturbances of approximately 1 mm wavelength are propagated in the arc, the potential fluctuations suggest that the associated electric fields are of the order of 400 V cm $^{-1}$ In the region of the constriction the oscillatory electric field might be expected to increase inversely as the diameter of the arc, giving a value of 6 × 10^3 V cm $^{-1}$ if allowance is made for the fact that the arc is smaller than the constricting aperture It is therefore possible that the ions gain their energy of several hundred electron volts from the oscillatory electric fields in the constricted region of the arc

Energetic ions of several hundred electron volts have been observed elsewhere[5] in high-current, low-pressure arcs in magnetic fields used in the DCX experiments However, the arc conditions are considerably different and the accelerating mechanism is not necessarily of the same kind as that proposed above

Acknowledgments are made to Mr J D Lawson, Prof A von Engels, Dr P C Thonemann and Dr S A Ramsden for their suggestions and interest, to Mr D H F Atkins for the activation analyses and to Mr F T Birks for the spectroscopic analyses of the ray deposits

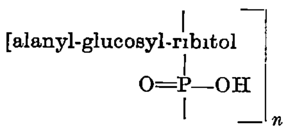
TEICHOIC ACIDS FROM BACTERIAL WALLS

FROM THE DEPARTMENT OF CHEMISTRY, KING'S COLLEGE (UNIVERSITY OF DURHAM), NEWCASTLE UPON TYNE

Composition of Teichoic Acids from a Number of Bacterial Walls

INVESTIGATIONS on the function of the nucleotides cytidine diphosphate glycerol[1] and cytidine diphosphate ribitol[2] led to the discovery of a new group of natural polymers, the teichoic acids, in the walls of certain bacteria[3] In *Bacillus subtilis* the teichoic acid is of the type shown in formula (1), whereas that in *Staphylococcus aureus* has the related structure (2), in which the sugar component is glucosamine That from *Lactobacillus arabinosus* is of the type (1), but some of the ribitol residues bear two glucosyl substituents, whereas others are unsubstituted by glucose A more detailed discussion of their structure and relationship with cytidine diphosphate ribitol has been given elsewhere[4]



$$\left[\begin{array}{c} | \\ \text{alanyl-glucosyl-ribitol} \\ | \\ \text{O}{=}\text{P}{-}\text{OH} \\ | \end{array}\right]_n$$

(1)

(3)

We had intended to confine the term 'teichoic acid' to those polymers of ribitol phosphate of the general structure (1) or (2) found in bacterial walls A more extended survey of other organisms (see Table 1) has shown that some bacteria contain a new type of teichoic acid in which ribitol has been replaced by glycerol Preliminary studies on the hydrolysis of these glycerol derivatives by acids, or by alkali followed by prostate phosphatase, show that they have the structure (3) Visual chromatographic estimation indicates that they represent more than 30 per cent of the wall in some cases Consequently, the restricted nomenclature originally adopted must now be modified to include all polymers of the types (1), (2) and (3)

The polyol phosphate derivatives in walls of *L arabinosus* and *B subtilis* are clearly ribitol-teichoic acids of the type (1), and no trace of a glycerophosphate polymer has been detected in these walls All strains of *Staph aureus* examined so far contain a ribitol-teichoic acid (2) ; but these walls also contain either traces, or in one case a considerable amount, of a glycerophosphate polymer Similarly, walls of *Streptococcus faecalis* contain a ribitol teichoic acid of the type (1) and a glycerophosphate polymer

It is interesting that *L casei*, *L delbruckii*, *L bulgaricus*, *Staph albus*, and *Staph citreus*, unlike the other lactobacilli and staphylococci examined so far, contain glycerol-teichoic acid but no trace of a ribitol-teichoic acid The compound from *Staph albus* and *Staph citreus* was present in their walls , but preparations from whole cells were used for the work on the three lactobacilli and it is not known whether the teichoic acid in these preparations originated from the walls The compound from *L casei* is of the type (3) in which alanine is attached to a polymer of glycerophosphate The amount of hexose in preparations of this material is very small and we have been unable to demonstrate any glycosylglycerol linkages It seems likely that all the glycerol–teichoic acids in the bacteria listed will be of type (3) , but the presence of glycosyl residues is still possible in some cases

In addition to the organisms discussed here, a number of others yielded small amounts of glycerophosphate on acid hydrolysis of their walls There is evidence that polyols other than ribitol and glycerol are present together with these in teichoic acid preparations from some organisms, and sugars other than glucose or glucosamine may occur

Extracts prepared from whole cells of all organisms examined contained a glycerophosphate polymer, even when no such polymer was present in the isolated walls It is not known whether this is a teichoic acid of type (3) which has been lost from the walls during their preparation or whether it is associated with other cell structures

In contrast to the variations in polyol and sugar, the only amino-acid found in purified preparations of teichoic acid is alanine This amino-acid isolated from teichoic acid from *L arabinosus* and *Staph aureus* has the D-configuration[5] It was shown earlier that the alanyl residues are in ester linkage and it is now found that the lability of these residues (half-life 5 min at 37°, *p*H 7 2, 1 1 *M* hydroxylamine) in neutral salt-free hydroxylamine solution is comparable to that of amino-acids bound to ribonucleic acid (half-life 3 min at 30°, *p*H 7 2, 0 8 *M* hydroxylamine)[6] The alanine ester linkages are therefore much more reactive than normal amino-acid esters which do not react significantly with hydroxylamine under comparable conditions[7]

Table 1

	Type of polymer	
	Glycerol	Ribitol
Lactobacillus arabinosus 17-5	–	+
L casei (A T C 7469)	+	–
L delbruckii (N C I B 8608)	+	–
L bulgaricus (N C I B 76)	+	–
Staphylococcus aureus H	trace	+
Staph aureus (Duncan)	trace	+
Staph aureus (Oxford)	+	+
Staph citreus	+	–
Staph albus (N C T C 7944)	+	–
Bacillus subtilis (vegetative form)	–	+
Escherichia coli (Type B)	trace	–
Corynebacterium xerosis	+	–
Streptococcus faecalis (A T C 9790)	+	+

D-alanine has been demonstrated as a characteristic component of a number of bacterial walls[8–10]. Snell, Radin and Ikawa[8] showed that in *Strep. faecalis* about 40 per cent of the D-alanine of the walls can be extracted with hot trichloroacetic acid in a bound form which is described as "especially labile to alkaline hydrolysis". The similarity in properties and method of extraction of this material and of teichoic acid suggests that these authors had obtained preparations containing teichoic acid.

The unifying feature in all teichoic acids is the presence of alanine ester linkages. If we confine this nomenclature to polymers of types (1), (2) and (3) containing such linkages, they are thus distinct from simple glycerophosphate polymers prepared from bacterial walls and membranes[11], although it is possible that the latter have originated from teichoic acids by loss of alanine groups during isolation.

We thank Drs. M. R. J. Salton, G. D. Shockman, E. P. Abraham and D. E. Hughes for samples of bacterial walls and for advice on their preparation. This work was supported by grants from the Medical Research Council, the Nuffield Foundation and the Rockefeller Foundation.

Structure of Teichoic Acid from the Walls of *Bacillus subtilis*

THE walls of *Bacillus subtilis* contain a large amount (about 50 per cent of their dry weight) of a teichoic acid[4] in which alanyl–glucosyl–ribitol residues are joined together through phosphate groups to form a polymer. Previous work had shown that each ribitol residue bears one glucosyl substituent and one alanine group in ester linkage with either a sugar- or ribitol-hydroxyl group. Recent findings indicate that the alanyl residues have the D-configuration in teichoic acid from *Staphylococcus aureus* and *Lactobacillus arabinosus*[5], and it is possible that the compound from *B. subtilis* will be a D-alanine derivative.

Hydrolysis of the teichoic acid from this organism with alkali and then prostate phosphomonoesterase gave a single glucosylribitol, but the scale of operations was small and this compound was not isolated[4]. From a larger-scale experiment crystalline glucosylribitol has been obtained in high yield, m.p. 137–138°, $[\alpha]_D$ − 28·6° (*c*, 0·1 in water) (found C, 41·8, H, 7·6. $C_{11}H_{22}O_{10}$ requires C, 42·0, H, 7·1 per cent). It seemed unlikely that the glucose was attached at the terminal 1(5)-position of the ribitol, since periodate oxidation, followed by reduction of products with sodium borohydride and then acid hydrolysis[12], gave glycerol but no ethylene glycol. Moreover, if the glucosyl residue was attached to position 3 in ribitol the compound should give a yellow colour on paper chromatograms sprayed, with the periodate-Schiff reagents for glycols[13]. The glucosylribitol gave the normal purple colour in this test, thus indicating the absence of the glucose at the 3-position.

The structure 4-β-D-glucopyranosyl-D-ribitol (4) was established by periodate oxidation. It consumed 4 mol. of periodate and gave 1 mol. of formaldehyde and 2 mol. of formic acid; it follows that the glucosyl substituent must occupy the 2- or 4-position on the ribitol. The compound was readily hydrolysed to glucose and ribitol by a β-glucosidase, and its specific rotation agrees well with those reported for β-D-glucosides.

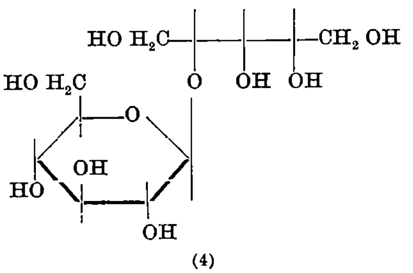
The trialdehyde formed by periodate oxidation contains two glyceraldehyde residues, one originating from the glucose and the other from the ribitol. That from the glucose must have the D-configuration, whereas that from the ribitol would have the D-configuration if the glucosyl substituent were originally at the 4-position on the ribitol, or the L-configuration if the glucosyl substituent were originally at the 2-position. Consequently, the structure (5), arising from 4-β-D-glucopyranosyl-D-ribitol (4), would be optically active, whereas the isomeric structure from 2-β-D-glucopyranosyl-D-ribitol would be a meso-compound.

The periodate-oxidation mixture exhibited a low positive rotation after removal of ions, even when kept for several hours under acidic conditions at room temperature. It was possible, however, that cyclic acetal formation in the trialdehyde might invalidate conclusions on its steric configuration. Consequently, the aldehyde was oxidized with bromine to the corresponding tricarboxylic acid. Without isolation this was hydrolysed with acid, and the resulting glyceric acid was examined polarimetrically as its ammonium salt in the presence of molybdate ions[14]. A positive rotation was observed even from the small amount (32·3 mgm.) of glucosylribitol used in these experiments. It follows that the trialdehyde has the structure (5), and hence the structure (4) is established for the original glucosylribitol.

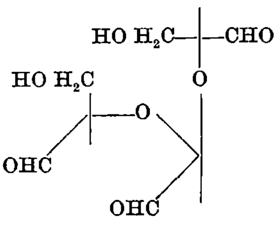
It is interesting that teichoic acids from different organisms may vary in the configuration of their glycosyl residues. The teichoic acid from *Lactobacillus arabinosus*[4], and the monoglucosylribitol obtained from it, are unaffected by β-glucosidase and have the specific rotations expected from α-glucosides (experiments with Dr. A. R. Archibald).

A sample of teichoic acid from *B. subtilis* was treated with ammonia under mild conditions to remove the alanine residues, and the product was oxidized for 24 hr. with periodate. Not more than a trace of anhydroribitol, and no ribitol derivatives, were detected in an acid-hydrolysate of the oxidation mixture, thus indicating the presence of unsubstituted glycol groups in the ribitol residues. It follows that the phosphodiester linkages must be situated at positions 1 and 5 or 3 and 5 on the 4-glucosylribitol units.

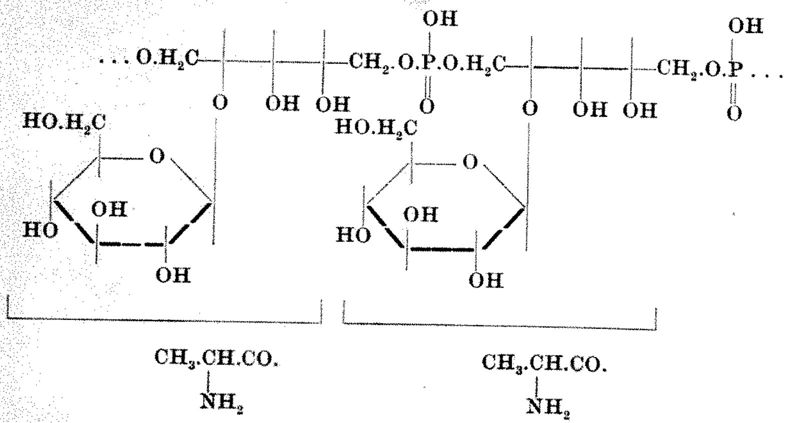
The teichoic acid in this organism almost certainly originates from cytidine diphosphate ribitol[2]. This nucleotide contains a D-ribitol 5-phosphate residue[13] which is apparently transferred intact into the polymer.



(4)



(5)



(6)

Alkaline hydrolysis of the teichoic acid occurred readily and completely, giving a mixture of monophosphates of glucosylribitol; only traces of diphosphates, and no phosphodiesters, were detected among the products. All the glucose was released from this mixture by a β-glucosidase, the other products being ribitol 1- and 2-phosphates; these phosphates were identified chromatographically[13]. It is noteworthy that the enantiomorphs, ribitol 5- and 4-phosphates, would be indistinguishable from the 1- and 2-phosphates on paper chromatograms, but nevertheless could not have been formed by the action of alkali on a polymer of 4-glucosylribitol 5-phosphate. As no trace of the readily identifiable ribitol 3-phosphate was detected among the products it follows that the phosphodiester linkages are at positions 1 and 5 in the polymer (6).

The structure (6) for this teichoic acid was confirmed by removal of alanyl residues with ammonia, purification of the resulting polymer by passage of the solution through a column of 'Dowex-50' resin, and oxidation with periodate. For every 3 mol. of periodate consumed, less than 0·2 mol. of formaldehyde was produced, thus indicating the almost complete absence of unsubstituted 1,2-(or 4,5-) glycol groups in the ribitol residues. The formaldehyde liberated in this experiment presumably originated in a terminal ribitol residue; but molecular weight estimations based on the amount of formaldehyde produced may not be reliable.

The presence of a trace of ribitol in a dephosphorylated alkali-hydrolysate of this teichoic acid suggests that a very small proportion of the ribitol residues in the polymer lacks the glucosyl substituent. The location of such residues, and the location of the highly reactive alanine ester groups, are not yet known.

RESIDUAL BODIES OF SEMINIFEROUS TUBULES OF THE RAT

By B. V. KINGSLEY SMITH and DR. D. LACY

Department of Zoology and Comparative Anatomy, St. Bartholomew's Hospital Medical College, University of London

JUST before sperms pass down the seminiferous tubules of the rat and various other mammals, they each cast off a small mass of material to which Regaud[1] gave the name "residual body". We have been investigating the formation, composition and fate of residual bodies with the view of determining their function. Modern histochemical and cytological techniques and both light and electron microscopy have been employed.

Light Microscope Observations

Evidence was obtained first which strongly suggested that residual bodies are of composite origin and structure. To clarify this problem, composite staining techniques of the kind described by Lacy[2] were utilized. Tissue was fixed according to the schedule given by Baker[3] and embedded in gelatine. Sections 3μ thick were affixed to gelatinized slides, and (*a*) impregnated with silver to show mitochondria[2], (*b*) coloured with sudan black *B* to show lipids, and (*c*) stained with pyronin-methyl green[4] to demonstrate basophilic material. The silver technique also revealed the Golgi remnant.

Within spermatids which had started to elongate we observed mitochondria, small lipoidal bodies, very fine basophilic granules and Golgi remnant. In older spermatids, with their elongate nuclei lying near the tubule lumen, we observed scattered mitochondria (distinct from those forming the mid-piece). Also present were lipoidal bodies generally of larger size than seen in younger spermatids, and aggregating to form mulberry-shaped clusters. Basophilic granules, less numerous but larger than in younger spermatids, and Golgi remnant, also occurred. At a later stage

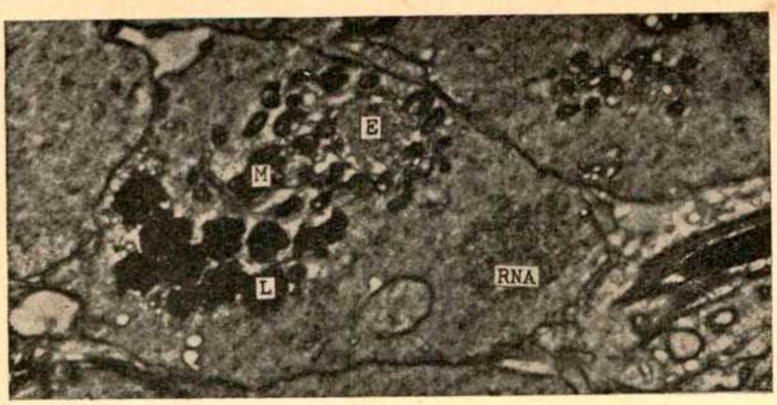

Fig. 1. Micrograph showing a late stage in the formation of a residual body. *E*, endoplasmic reticulum; *L*, lipoidal body; *M*, mitochondrion; *RNA*, aggregate of particles containing ribonucleic acid. (× *c*. 7,300)

in spermatid development all the above-mentioned inclusions had concentrated within a small lobe of cytoplasm near the base of the nucleus. Just before the mature spermatid is shed, this lobe of cytoplasm is cast off and becomes spheroidal in shape. The spheroidal bodies which arise in this way clearly correspond to the residual bodies of Regaud. Each residual body is bounded by a membrane derived from the cell membrane of the corresponding mature spermatid. Within, and close to, the limiting membrane lie two or three small groups of granular mitochondria, several lipoidal bodies (sometimes arranged in crescent fashion) and Golgi remnant. The greater part of each residual body is occupied by a comparatively large, eccentrically placed mass of strongly basophilic material.

Soon after the sperms have been shed the residual bodies migrate peripherally. As precisely as could be determined by light microscopy, this appeared to be due to phagocytosis by Sertoli cells. Afterwards, the residual bodies come to lie close to Sertoli nuclei at the border of the tubule.

Changes occur within the residual bodies both during their peripheral migration and while they are at the periphery of the tubule. The first sign of these changes is the appearance of minute vesicles about $0{\cdot}3\mu$ in diameter which form along the edges of the basophilic material. During their movement towards the periphery the residual bodies become reduced in size, their diameter decreasing from about 10μ to 5μ. Finally, there is a loss in basophilia and then all that can be seen is the limiting membrane, some mitochondria and lipoidal bodies, and the Golgi remnant. After this stage it is impossible to identify the residual bodies with any certainty. However, accompanying and following upon the 'end' stage, lipoidal bodies of about the same size as the residual bodies, and in the same general location, appear within the Sertoli cells. We have studied the residual bodies at this time to see if they become converted into the lipoidal bodies described above. What may be transitional stages have, in fact, been observed, but only very rarely.

Histochemical tests have shown that the basophilic material referred to above consists of, or contains, ribonucleic acid. The lipoidal bodies which occur within spermatid cytoplasm, and form part of the residual bodies, do not respond positively to Baker's[5] acid hæmatin test for phospholipins nor to Schultz's[6] test for cholesterol. The same negative responses for both tests are also given by the lipoidal bodies within Sertoli cells.

Electron Microscope Observations

Tissue was fixed in 1 per cent osmium tetroxide buffered to *p*H 7·3[7]. It was then embedded in a 1 : 3 mixture of *n*-methyl and *n*-butyl methacrylate, sectioned with a glass knife and examined in a Siemen's Elmiskop I*a*. Due to the comparatively small size of the residual bodies and the fact that they occur only under certain physiological conditions a great deal of material has had to be examined to find even the more important stages referred to above.

Observations made by electron microscopy are in accord with those made by light microscopy. In addition, finer details have been seen. During late formative stages (Fig. 1) the mitochondria are irregular in shape and characteristically cluster around a local concentration of endoplasmic reticulum. Adjacent to these elements is a group of osmiophilic granules which correspond to the lipoidal bodies seen under the light microscope. The Golgi remnant consists of a few paired membranes in parallel arrangement and aggregates of many small vesicles enclosed by two or more membranes. Near the inclusions just described occur one or two particulate masses, spheroidal in general outline and corresponding to the ribonucleic acid granules seen by light microscopy. At a later stage in the formation of the residual bodies the mitochondria are either greatly elongated and constricted in the middle (as though in a process of division) or are small, dense and spheroidal. The endoplasmic reticulum appears to consist of membranes delimiting vacuoles of various sizes. The basophilic material consists of one large mass of fine particles.

Studies by electron microscopy have confirmed quite definitely that the residual bodies are phago-

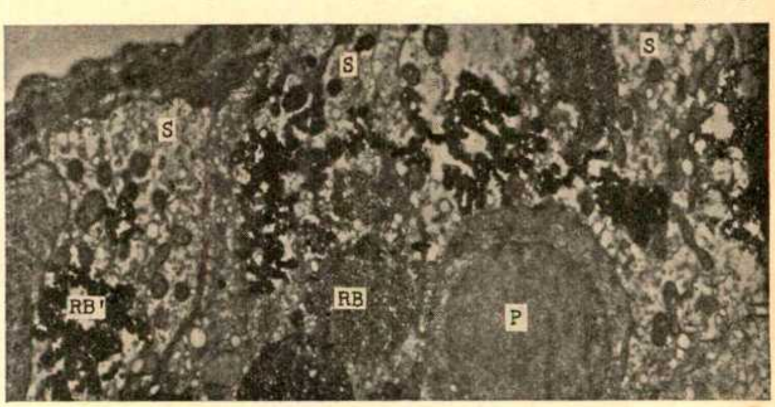

Fig. 2. Micrograph showing residual bodies within Sertoli cells at the border of a tubule. Some of the residual bodies (*RB*) are comparatively intact. Others have been largely absorbed and appear irregular in shape (*RB'*). *P*, primary spermatocyte; *S*, Sertoli cell. (× *c*. 7,300)

cytosed by the Sertoli cells Within any one Sertoli cell, even in ultra-thin sections, we have observed up to six residual bodies Each residual body is enclosed by a variable number (1–4) of fine membranes When the body reaches the edge of the tubule the limiting membranes are no longer continuous Residual bodies at the periphery contain the same basic constituents as those seen in the last stages of their formation in the tubule lumena Later, the basophilic material and various other components are absorbed until all that remains is an irregular-shaped body which is intensely osmiophilic and presumably lipoidal (Fig 2) About this time a peripheral ring of lipid can be demonstrated in Sertoli cells by the use of appropriate light microscopical techniques

When the residual bodies come to lie close to the Sertoli nuclei (adjacent to the tubule tissue) changes occur both within the Sertoli cytoplasm and in germ cells Within the Sertoli cells appears the peripheral ring of lipid mentioned above Mitochondria either increase in number or become concentrated peripherally The cytoplasmic matrix (as seen under the electron microscope) becomes very dense The young spermatids start to elongate and become more deeply enclosed by Sertoli cytoplasm There is an increase in chromatin content of the nuclei of type *B* spermatogonia It is possible that the residual bodies produce in the Sertoli cells some influence that may serve to trigger off the changes in the germ cells as reported above The residual bodies would then be responsible for the local control of spermatogenesis This is now being investigated further

We are grateful to the Wellcome Trust for a grant to purchase an electron microscope and to St Bartholomew's Hospital and Medical College for further financial help

GROWTH RESPONSES TO SELENIUM IN LAMBS

By Dr J W. McLEAN, G. G THOMSON and J. H CLAXTON
Canterbury Agricultural College, Christchurch, New Zealand

UNTIL recently, selenium as a dietary constituent was regarded as of significance only when it occurred in excess of certain well-defined limits In selenium poisoning areas, about 5 p p m in herbage is considered to be the tolerance limit for livestock[1] It has now been shown[2–5] that selenium in organic and inorganic form has high protective powers against necrotic liver degeneration in the rat and mouse, and exudative diathesis in the chick fed basal diets deficient in vitamin E and containing a high proportion of *Torula* yeast , protection being obtained respectively with 0 04 p p m and 0 1 p p m of selenium in the ration It has been shown also in the chick that selenium is a required nutrient necessary for normal growth as well as for the prevention of exudative diathesis[6]

So far as large animals are concerned, there is evidence to indicate that sodium selenite fed to pregnant ewes at the rate of 0 1 p p m of selenium in the ration will protect their lambs against muscular dystrophy (white muscle disease)[7,8]

Furthermore, trials conducted in the South Island of New Zealand[9] suggest a protective action of selenium when given to the lambs themselves, in naturally occurring outbreaks of a type of muscular dystrophy affecting young lambs

Arising from the idea that subclinical muscular dystrophy might be one of the factors responsible for the slow growth-rate of weaned and unweaned lambs commonly observed in the South Island—a condition known locally as 'ill-thrift'—we commenced trials to investigate the possible effects of selenium supplements on the growth-rate of various classes of lambs on the College farms This communication records the observations made to date

All lambs were individually identified with ear-tags, divided at random into treatment and control groups, and weighed at intervals of 2–3 weeks Selenium was given as sodium selenate by subcutaneous injection in sterile water at the rate of 1 0 mgm selenium every 7–10 days Lambing commenced about the beginning of August, and weaning occurred in the first week of December

The first three trials involved pure-bred Romney, Border Leicester and Corriedale ram and ewe lambs reared on the College home farm The fourth trial was carried out on Corriedale wether lambs brought on to the College farm from the same farm on which the fifth trial was conducted (Ashley Dene farm)

Mean live weights and gains are set out in Table 1, with the numbers of lambs in each group given in brackets

Table 1 MEAN LIVE WEIGHTS AND GAINS (LB)

Trial 1	Romneys			
	Date	9 10 58	22 1 59	Gain
	Selenium	30 5 (94)	69 4	38 9
	Control	31 5 (88)	66 3	34 8
	Difference in 105 days			4 1**
Trial 2	Border Leicesters			
	Date	19 10 58	22 1 59	
	Selenium	51 2 (49)	79 2	28 0
	Control	50 3 (47)	71 9	21 6
	Difference in 95 days			6 4**
Trial 3	Corriedales			
	Date	21 11 58	22 1 59	
	Selenium	46 6 (61)	63 1	16 5
	Control	47 4 (59)	60 9	13 5
	Difference in 62 days			3 0**
Trial 4	Corriedale wethers			
	Date	11 11 58	12 2 59	
	Selenium	52 2 (20)	74 5	22 3
	Control	52 2 (20)	67 8	15 6
	Difference in 93 days			6 7**
Trial 5	Corriedale (mixed sex)			
	Date	3 11 58	2 2 59	
	Selenium	40 6 (23)	78 3	37 7
	Control	41 6 (21)	68 6	27 0
	Difference in 91 days			10 7**

** Significant at 1 0 per cent level

Analysis of variance shows that the differences in gains in live weight are highly significant ($P < 0\ 01$) in all trials The magnitude of these responses varies considerably, being greater in general in the lambs from the Ashley Dene farm The response is rapid, evidence of increased growth being observable in all groups in 2–3 weeks after treatment commenced.

Further, it appears to be a continuing one, although the duration of some of the trials is obviously short

Explanation of the mode of action of selenium in producing a growth response under these conditions must at the present time be rather speculative There can be little doubt now that traces of selenium are required by the animal for normal metabolism, that vitamin E and selenium are interrelated in their metabolic functions, and that vitamin E cannot completely replace the need for selenium The growth responses in lambs may therefore be taken as an indication of a specific selenium deficiency, one manifestation of which is a slowing up of growth, and another a predisposition to muscular dystrophy and possibly other conditions in which the metabolism of vitamin E is involved

This concept is in conformity with the known distribution of naturally occurring outbreaks of exudative diathesis in chicks and white muscle disease in lambs[10], both of which, in New Zealand, are almost entirely restricted to the South Island

In this respect it is of interest to note that the groups of lambs giving the greatest response (trials 4 and 5) came from flocks in which losses from white muscle disease had occurred earlier in the season before these trials commenced (4 out of 600 for trial 4 and 7 out of 51 in trial 5)

At the other extreme, in the pure-bred lambs on the College farm, only one death occurred from white muscle disease ; there were no other signs of the disease in the 580 lambs born this season, nor has there ever been any history of the disease on this farm Selenium responses have therefore been obtained, not only in lambs from areas where white muscle disease is common, but also where it has been extremely rare

On the other hand, the College farm has had a history of so-called 'ill-thrift' of varying degrees of severity over the past three years Just what part, if any, selenium deficiency plays in the 'ill-thrift' syndrome in this area is not as yet clear That it may be a factor of some importance is indicated by the data presented in these trials

This is a preliminary report only and final results will be published elsewhere

CARBOHYDRATE—AMINO-ACID INTER-RELATIONS IN BRAIN CORTEX *IN VITRO*

By M M KINI and PROF J H QUASTEL, F R S

McGill-Montreal General Hospital Research Institute, 3619 University Street, Montreal

IT is now well known that when radioactive glucose is metabolized by brain cortex *in vitro*, radioactive amino-acids are formed[1–5] A mince of the brain of one-day-old mice when incubated with glucose uniformly labelled with carbon-14 incorporates radioactivity in all amino-acids of brain protein with the exception of threonine[1] Rat brain cortex slices can convert ^{14}C-glucose into labelled glutamic, aspartic and γ-aminobutyric acids[3] When ^{14}C-glucose is injected intraperitoneally into one-day-old mice, radioactivity is found in aspartic and glutamic acids and in alanine in the brain proteins[3] It is evident that glucose, during its normal metabolism in the brain, produces intermediates—presumably the α-ketonic acids—that undergo conversion to amino-acids largely at the expense of organic nitrogen already available in the brain cell Such amino-acids must play a part not only in the various biosynthetic operations of the nerve cell but also in the maintenance of ionic balance in the cell It is therefore of importance to understand more fully than is known at present the precise relations existing between sugars and amino-acids in the brain, and the manner in which these relations may be affected by substances that influence brain metabolism Among such substances are potassium ions, which have long been known to exert profound effects on the metabolism of nerve cells Cationic balance is a factor of fundamental importance for the metabolism of brain, both aerobically[6] and anaerobically[7]

We have therefore carried out experiments to ascertain the effects, on the formation of amino-acids from glucose in the brain cortex *in vitro*, of those concentrations of potassium ions that produce optimal stimulation of respiration, of a neurotropic drug such as amytal and of a respiratory inhibitor such as sodium malonate The experiments have been carried out not only to throw more light on the mode of action of these substances but also to indicate the importance of the consideration of the amino-acids as part of the over-all metabolism of sugars in the nervous system

The experimental work was carried out with the conventional Warburg manometric apparatus Slices of rat brain cortex weighing approximately 90 mgm were incubated in a medium of the following composition sodium chloride, 128 m*M* , potassium chloride, 5 m*M* , calcium chloride, 3 6 m*M* , magnesium sulphate, 1 3 m*M* , disodium hydrogen phosphate, 10 m*M* brought to *p*H 7 4 with *N* hydrochloric acid The final volume was 1 0 ml. and each flask contained 5 m*M* glucose uniformly labelled with carbon-14 with an activity of 10^6 counts/min when counted on aluminium planchets at infinite thinness 0 1 ml. of 20 per cent potassium hydroxide was used as carbon dioxide absorbent Incubations were carried out in oxygen at 37° C for 1 hr , after which the tissue slices were homogenized in 8 0 ml of 80 per cent ethanol, centrifuged and the supernatant evaporated at 30° C in a current of air The dried extract was dissolved in 0 5 ml of water and 400 µl was chromatographed two-dimensionally on Whatman No 1 paper The solvents used were *sec* butanol/90 per cent formic acid/water (70 11 17 v/v/v) for the first phase, and phenol/water/ammonia (1 lb phenol 110 ml water 1 7 ml ammonia, spec grav. 0 88) for the second phase

The radioactive spots were localized by radioautography and the radioactivities of the spots were measured quantitatively using a 'Tracerlab' counter with a mica window 28 mm in diameter and thickness 1 5–1 8/cm ^{2} Activities were corrected for background The counting efficiency by this method was calculated to be 16 8 per cent

All results are expressed as counts per minute for 100 mgm of wet-weight tissue

Effects of Potassium Ions on Amino-acid Formation from Glucose and Fructose

The stimulating effects of potassium ions at 105 m*M* (preferably expressed as meq /litre (milliequivalents/litre)) on brain respiration, shown many years ago by Dickens and Greville[8] and by Ashford and Dixon[9], take place with the identical substrates, glucose, pyruvate or lactate, which permit responses to applied electrical pulses The potassium effect has many of the metabolic characteristics of brain tissue in the excited state It is suppressed by low concentrations of narcotics that have no demonstrable effects on the unstimulated respiration in the presence of glucose, which is quantitatively the most important metabolic fuel of the brain[10,11] and of ganglia[12] The narcotic suppression of potassium stimulation of brain respiration applies not only to central narcotics[13] but also to local anæsthetics[14], to chlorpromazine, alcohols and aldehydes[15,16] and to the newer depressants of the glutarimide type, and focuses interest on the mechanism of potassium stimulation of neurone respiration This stimulation seems greatly to resemble that brought about by oscillating electrical pulses[17,18], which may produce their effects by ionic displacements, for example, of potassium, calcium or sodium All the evidence points, in fact, to the similarity in many respects of the biochemical effects of electrical stimulation of the brain cortex slice with those due to the presence, in the incubation medium, of potassium ions at 0 1 molar concentration Brain homogenates or minces are, as is well known, unresponsive to either forms of activation Presumably in the conscious animal such stimulation operates by the action of sensory impulses, and high sensitivity to narcotics of the metabolic activity of the stimulated brain cell ensues

The potassium stimulation of brain respiration is highly sensitive to malonate, whereas unstimulated brain respiration is but little affected by malonate[19,20] It is evident[6,16] that potassium ions activate the citric acid cycle involved in glucose oxidation in the brain or a pace-making step closely associated with it

Results showing the effects of the addition of 105 m*M* potassium chloride solution to the incubation medium on amino-acid formation in rat brain cortex slices are shown in Table 1 It will be seen that in a normal physiological medium containing 5 m*M* potassium ions there is a labelling of glutamic acid, aspartic acid, glutamine, alanine and γ-aminobutyric acid in the presence of glucose and of fructose both uniformly labelled with carbon-14 The labelling of glutamic acid, with both sugars, is highest among the amino-acids investigated, aspartic acid showing the next highest activity It is noteworthy that the labelling of aspartic acid, on incubation with uniformly labelled fructose. greatly exceeds that of aspartic acid found after incubation with uniformly labelled glucose

Table 1 EFFECTS OF 0 1 *M* POTASSIUM CHLORIDE ON AMINO-ACID PRODUCTION FROM GLUCOSE AND FRUCTOSE UNIFORMLY LABELLED WITH CARBON-14 IN SLICES OF RAT BRAIN CORTEX

Substrate concentration, 5 m*M* (10^6 counts/min), incubation time, 60 min , temperature, 37° C , aerobic All values are expressed as counts/min /100 mgm wet tissue/10^6 counts/min uniformly labelled substrate per vessel

Amino-acid formed	Glucose-U-^{14}C		Fructose-U-^{14}C	
	5 m*M* K$^+$	105 m*M* K$^+$	5 m*M* K$^+$	105 m*M* K$^+$
Glutamic acid	5,057 ±358	5,516 ±475	4,784 ±307	942 ± 21
Aspartic acid	1,318 ±164	1,183 ±185	2,159 ±122	2,127 ±104
Glutamine	1,289 ±112	2,397 ±209	(*)	(*)
Alanine	657 ± 60	794 ± 49	374 ± 63	224 ± 24
γ-Amino-butyric acid	966 ±142	1,491 ±164	739 ± 22	271 ± 10

All values are given with mean standard errors

* Glutamine could not be counted, when fructose was used as substrate, as the fructose spot overlapped that of glutamine

The most important quantitative effect of the presence of 105 m*M* potassium ions, which increases the respiration of brain cortex slices in the presence of glucose by almost 100 per cent, is to bring about a large increase in the labelling of glutamine (nearly 100 per cent) and of γ-aminobutyric acid The total count of the labelled amino-acids in the presence of glucose uniformly labelled with carbon-14 is increased from 9,287 to 11,381 counts/min The labelling of glutamic acid or alanine is slightly increased whereas that of aspartic acid is slightly decreased

It may be noted that the ratios of radioactive glutamate, glutamine and γ-aminobutyrate found with potassium-stimulated rat brain-cortex slices in presence of glucose are 1 0 44 0 27 (Table 1), which approximate to the ratios of these amino-acids normally found in the adult rat brain cortex[31], namely, 1 0 43 0 17

As it is well known that glutamine is derived from glutamate in brain in a reaction involving adenosine triphosphate[21], the process bringing about the removal of free ammonium ions that are liberated during the functional activity of the brain[22], and that γ-aminobutyric acid is derived from glutamate by a decarboxylase normally present in the brain[23], we may consider that the net effect of exposing brain-cortex slices in presence of glucose, uniformly labelled with carbon-14, to 105 m*M* potassium ions, is to increase the total yield of glutamic acid, the excess over the normal appearing as both glutamine and γ-aminobutyric acid This phenomenon may be explained by the fact that the presence of 105 m*M* potassium ions accelerates the operation of the citric acid cycle in the brain, increasing the rate of turnover of intermediates, among which is α-keto-glutarate which, by transamination with intracellular amino-acids, forms glutamate and thence glutamine and γ-aminobutyric acid

Typical results given in Table 2 lead to the conclusion that the presence of potassium ions accelerates the conversion of pyruvate to acetyl-coenzyme *A* The results demonstrate that the presence of 105 m*M* potassium ions greatly increases the rate of oxidation in brain cortex of both pyruvate-1-^{14}C and pyruvate-2-^{14}C to carbon-14 dioxide, the latter process being much more inhibited by the presence of malonate than the former The fact that some inhibition

Table 2 COMPARISON OF THE EFFECTS OF 0 01 *M* SODIUM MALONATE AND 0 1 *M* POTASSIUM CHLORIDE ON OXIDATION OF PYRUVATE-1-^{14}C AND PYRUVATE-2-^{14}C BY SLICES OF RAT BRAIN CORTEX

Substrate concentration, 10 m*M* (10^5 counts/min), incubation time 60 min , temperature, 37° C , aerobic Carbon-14 dioxide evolved expressed as counts/min /mgm dry weight tissue/hr /10^6 counts/min substrate per vessel

Experimental conditions	Pyruvate-1-^{14}C		Pyruvate-2-^{14}C	
	5 m*M* K$^+$	105 m*M* K$^+$	5 m*M* K$^+$	105 m*M* K$^+$
Sodium pyruvate only	1,166	2,008	481	1,040
Sodium pyruvate + 0 01 *M* sodium malonate	903	1,342	258	336

of the former process by malonate occurs leads to the conclusion that part of the carbon-14 dioxide derived from pyruvate-1-^{14}C is formed after its fixation and metabolism by the citric acid cycle

Granting that the effect of the presence of 105 m*M* potassium ions is an increased rate of formation of acetyl-coenzyme *A*, it becomes at once apparent (see Fig 1) that the rate of formation of α-ketoglutarate (and thereby the rates of formation of glutamate, glutamine and γ-aminobutyrate) should be increased, whereas that of oxalacetate (and thereby aspartate) may not be increased, as its greater rate of formation is balanced by its greater rate of removal by condensation with the increased quantity of acetyl-coenzyme *A* that has become available

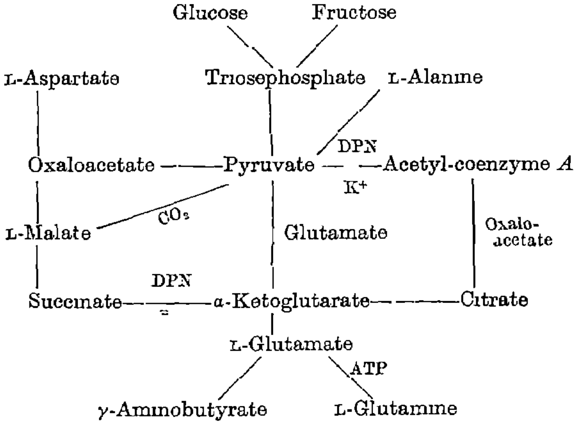

Fig 1

The conclusion that the major effect of increased potassium ions is to increase the velocity of formation of acetyl-coenzyme *A* from pyruvate in brain cortex makes it possible to understand the mode of action of potassium ions in affecting the formation of amino-acids from fructose uniformly labelled with carbon-14 It will be seen, in the results quoted in Table 1, that in the presence of the normal potassium ion concentration (5 m*M*), there is a marked increase of labelled aspartate and a marked decrease of labelled alanine as compared with the amounts of these amino-acids formed in the presence of glucose uniformly labelled with carbon-14 When the potassium ion concentration is increased to 105 m*M*, the outstanding effects are the large falls in the amounts of labelled glutamate and γ-aminobutyric acid Owing to experimental difficulties, when using fructose on paper chromatograms, it was not possible to make accurate assays of the radioactive glutamine formed

The significant factor to be taken into account in interpreting the results found with uniformly labelled fructose (Table 1) is the much lower affinity of fructose for brain hexokinase than that of glucose[24] The result of this lower affinity is a diminished availability of pyruvate in the brain cortex slices, under the experimental conditions quoted, a fact that accounts for the feeble anaerobic glycolysis exhibited by brain cortex in presence of fructose Sufficient pyruvate is available, however, to enable the citric acid cycle to operate and to yield a respiratory value of the same order as shown by glucose in presence of brain cortex The lack of availability of pyruvate, apart from that amount required for the citric acid cycle to operate, is also shown by the much lower ability of brain cortex slices to form lactic acid or to synthesize acetyl choline in presence of fructose as compared with that found in the presence of glucose[25] Although respiratory activities, and presumably, therefore, the amounts of available adenosine triphosphate, of brain cortex slices in the presence of glucose and fructose are approximately the same, the rate of formation of acetyl-coenzyme *A* in the presence of the former sugar is greater than in the presence of the latter

The lowered availability of pyruvate, in brain cortex slices in the presence of fructose uniformly labelled with carbon-14, results in there being less acetyl-coenzyme *A* available for condensation with oxalacetic acid formed during the operation of the citric acid cycle This in turn leads to more oxalacetic acid being available for transamination into aspartic acid than occurs with glucose On this interpretation, the larger yields of labelled aspartic acid found in the presence of uniformly labelled fructose than in the presence of uniformly labelled glucose is directly due to lack of available acetyl-coenzyme *A* for the acetylation of oxalacetic acid The lowered availability of pyruvic acid from uniformly labelled fructose is shown also by the diminished rate of formation of labelled alanine (Table 1) in the presence of this sugar

The effects of an increased concentration of potassium ions on amino-acid formation from fructose may also be understood The acceleration of conversion of pyruvate to acetyl-coenzyme *A* by the presence of 105 m*M* potassium ions leads to an increased rate of respiration, so that more of the limited pyruvate available is converted to carbon dioxide There is therefore less pyruvate available for conversion to amino-acids Experiment shows (Table 1) that a total count of 8,056 counts/min for the amino-acids investigated falls to 3,564 counts/min in the presence of 105 m*M* potassium ions

The limited amount of pyruvate, made available from fructose, leads ultimately to the formation of a smaller quantity of α-ketoglutarate than takes place with glucose, in spite of the increased rate of formation of acetyl-coenzyme *A* due to the presence of 105 m*M* potassium ions This in turn leads to smaller amounts, at equilibrium, of labelled glutamate and γ-aminobutyrate The quantity of labelled aspartate formed, however, remains approximately constant This occurs, presumably, because the malic acid enzyme that transforms pyruvate to malate with fixation of carbon dioxide, and thence to oxalacetate and aspartate, is operating optimally This process is already known to occur with retina[28] and with mouse brain[30]

It is therefore possible to obtain an understanding of the relations existing between glucose or fructose, and the amino-acids derived from these sugars in the brain, both in the presence of normal and high concentrations of potassium ions, on the basis of our present knowledge of the operations of the citric acid cycle in brain, of transaminating processes affecting the α-ketonic acids, and on the conclusion that the stimulating action of potassium is largely directed to the conversion of pyruvate into acetyl-coenzyme *A*.

The implications of these findings are considerable, for they indicate that cationic balance, by influencing the relative velocities of the neurochemical processes, affects the formation of substances, such as acetylcholine or γ-aminobutyric acid, which are now well known to be implicated in the electrophysiology of the nervous system.

Effects of Sodium Malonate on Glucose–Amino-Acid Inter-relations

In the presence of 10 m*M* sodium malonate, the respiration of brain cortex stimulated by potassium is inhibited to the level of the endogenous respiration, which is only slightly affected.

The effects of the addition of 10 m*M* sodium malonate on the formation of labelled amino-acids from glucose uniformly labelled with carbon-14 are shown in Table 3.

Table 3. INFLUENCE OF 0.01 *M* SODIUM MALONATE ON AMINO-ACID FORMATION FROM GLUCOSE UNIFORMLY LABELLED WITH CARBON-14 WITH AND WITHOUT 0.1 *M* POTASSIUM CHLORIDE

Experimental conditions as in Table 1. Results (counts/min./100 mgm. wet tissue/10^6 counts/min. glucose) are the mean values of three sets of experimental results

Amino-acid formed	5 m*M* K^+ + 0.01 *M* malonate	105 m*M* K^+ + 0.01 *M* malonate
Glutamic acid	1,990	995
Aspartic acid	328	583
Glutamine	361	72
Alanine	133	60
γ-Aminobutyric acid	522	194

The most noteworthy effect of the malonate is the decrease in labelling of all the amino-acids; a total amino-acid count of 9,287 counts/min. is reduced by malonate to 3,334 counts/min. The percentage decrease effected by malonate is greater in the presence of 105 m*M* potassium ions. The total count of 11,381 counts/min. found with the high potassium ion concentration is reduced to 1,904 counts/min. when the malonate is added. Thus not only is the potassium stimulation of brain respiration abolished by malonate[13], but also its stimulation of amino-acid labelling in the presence of radioactive glucose. The suppression of respiration is reflected by the lowered availability of pyruvate, and hence in the diminished production of labelled alanine and of α-ketoglutarate, and hence in the diminished rates of formation of glutamate, glutamine and γ-aminobutyric acid.

Effects of Sodium Amytal on Amino-acid Formation from Glucose

In accordance with the conclusion by Michaelis and Quastel[27] that a narcotic, such as chloretone, suppresses specifically at low concentrations the activity of a process playing an intermediate part in tissue respiration between a flavoprotein involving diphosphopyridine nucleotide, and cytochrome oxidase, it has been shown[28] that amytal (5-ethyl-5-*iso*amyl barbiturate) is a highly effective inhibitor of the oxidation of reduced diphosphopyridine nucleotide and its associated phosphorylations.

An effect, therefore, of the addition of a narcotic, such as amytal, to respiring tissue is to bring about an increase in the ratio of reduced diphosphopyridine nucleotide to diphosphopyridine nucleotide in the cell. The change in this ratio, or the diminished availability of diphosphopyridine nucleotide for its various linked reactions in cell metabolism, has a variety of consequences. One obvious result is an increase in the rate of reduction of pyruvate, derived from aerobic breakdown of glucose in the brain cell, to lactate, so that an increased aerobic glycolysis in the presence of the narcotic takes place. This is a well-known phenomenon[29]. Other results, due both to the changed velocities of the diphosphopyridine nucleotide-linked reactions and to the diminished availability of adenosine triphosphate consequent upon the suppression of oxidation of reduced diphosphopyridine nucleotide, may be expected to take place.

The effects of the addition of 0.5 m*M* sodium amytal on amino-acids formed from glucose, uniformly labelled with carbon-14, in the presence and absence of 105 m*M* potassium ions are shown in Table 4. At this concentration, amytal exerts only a small inhibitory effect on the oxidation of glucose by the unstimulated brain cortex slices but almost a complete suppression of the potassium-stimulated respiration of brain cortex in the presence of glucose[6]. The results (Table 4) demonstrate these effects.

Table 4. INFLUENCE OF 0.5 m*M* SODIUM AMYTAL ON AMINO-ACID FORMATION FROM GLUCOSE UNIFORMLY LABELLED WITH CARBON-14 WITH AND WITHOUT 0.1 *M* POTASSIUM CHLORIDE

Experimental conditions as in Table 1

Amino-acid formed	5 m*M* K^+ + glucose-U-^{14}C 0.5 m*M* amytal	105 m*M* K^+ + glucose-U-^{14}C 0.5 m*M* amytal
Glutamic acid	5,793 ± 335	6,761 ± 450
Aspartic acid	1,002 ± 65	661 ± 51
Glutamine	1,095 ± 80	111 ± 10
Alanine	1,104 ± 70	386 ± 36
γ-Aminobutyric acid	1,798 ± 45	1,479 ± 123

(*a*) In normal physiological media (5 m*M* potassium ions) the presence of 0.5 m*M* amytal produces a marked increase in the rates of formation of labelled γ-aminobutyric acid and alanine, with relatively small changes in the rates of appearance of labelled glutamate, aspartate and glumatine.

(*b*) In the presence of 105 m*M* potassium ions and 0.5 m*M* amytal, there is a very large fall in the rate of formation of labelled glutamine from 2,397 counts/min. (Table 1) to 111 counts/min. (Table 4). There is a fall also in the rate of formation of labelled alanine and aspartic acid and a rise in that of glutamic acid.

The results may be explained in the following manner.

(1) With the unstimulated slice of brain cortex, the amytal brings about a diminution of available diphosphopyridine nucleotide, so that less pyruvate is oxidized to acetyl-coenzyme *A* and less α-ketoglutarate is converted to succinate. There is not only, therefore, an increased rate of conversion of pyruvate to lactate but also an increased rate of conversion, by transamination, of labelled pyruvate to alanine and of labelled α-ketoglutarate to glutamate. The latter reaction is reflected in an increased rate of formation of labelled γ-aminobutyrate. The rate of formation of glutamine is not increased; it is in fact decreased, presumably because the suppression of oxidation of reduced diphosphopyridine nucleotide, leading to a diminished synthesis of adenosine tri-

phosphate, results in a diminished amount of the latter being available for synthesis of glutamine

(2) With the stimulated slices of brain cortex, in which the oxidation of pyruvate by diphosphopyridine nucleotide to acetyl-coenzyme *A* is greatly enhanced, the effect of the presence of the narcotic is to suppress this oxidation owing to the lowered availability of diphosphopyridine nucleotide The increase of reduced diphosphopyridine nucleotide leads to an increased rate of formation of lactate (that is, increased aerobic glycolysis), this process taking place partly at the expense of pyruvate that would otherwise be transformed to alanine A similar suppression of oxidation of α-ketoglutarate leads to enhanced labelling of glutamate The synthesis, however, of glutamine from glutamate is almost entirely blocked by the narcotic, by its suppression of synthesis of adenosine triphosphate normally coupled with the oxidation of reduced diphosphopyridine nucleotide

It is evident that the processes controlling glucose – amino-acid inter-relations in both the unstimulated and stimulated slice of brain cortex and in the absence or presence of a narcotic such as amytal may be interpreted satisfactorily on the basis of the conclusions that the stimulation consists of an acceleration of the conversion of pyruvate to acetyl-coenzyme *A* and that the narcotic brings about a suppression of endogenous oxidation of diphosphopyridine nucleotide by cytochrome oxidase and its associated phosphorylations

Summary

(1) Glucose and fructose, both uniformly labelled with carbon-14, in the presence of slices of rat brain cortex, are partly converted to radioactive glutamic acid, glutamine, γ-aminobutyric acid, aspartic acid and alanine The yields, and relative proportions, of these amino-acids found with the uniformly labelled glucose differ considerably from those found with uniformly labelled fructose An outstanding difference is the large yield of labelled aspartic acid found with fructose as compared with that from glucose

(2) When brain cortex respiration in the presence of glucose or fructose is stimulated by the addition of 105 m*M* potassium ions, large changes take place in the yields and relative proportions of radioactive amino-acids With glucose, the effect is greatly to increase the yield of glutamine and γ-aminobutyric acid With fructose, the effect is greatly to diminish the yield of labelled glutamate

(3) It is concluded, from the effects of the addition of 105 m*M* potassium ions on the formation of carbon-14 dioxide from pyruvate-1-^{14}C and pyruvate-2-^{14}C, and on the relative inhibitory effects of malonate on these processes, that the stimulating effect of addition of potassium ions on the respiration of brain cortex is largely directed to an acceleration of a pace-making step, the conversion of pyruvate to acetyl-coenzyme *A*

(4) The presence of malonate, which abolishes the potassium ion stimulation of respiration of brain cortex, brings about a greatly diminished labelling of all amino-acids derived from glucose, uniformly labelled with carbon-14, and in the presence of added potassium ions almost completely blocks the formation of alanine, glutamine, and γ-aminobutyric acid

These results can be satisfactorily explained on the basis of the conclusions that the amino-acids are derived from glucose by transamination of the α-ketonic acids derived during the operation of the citric acid cycle and that the potassium ion stimulation of the metabolism of brain cortex is due to it acceleration of the oxidation of pyruvate to acetyl-coenzyme *A*

(5) The presence of the narcotic, 0 5 m*M* sodium amytal, produces, with the unstimulated brain cortex slice, a marked increase in the yield from glucose uniformly labelled with carbon-14, of labelled γ-aminobutyric acid and alanine, with relatively small changes in the yields of labelled glutamate, aspartate and glutamine With the stimulated brain cortex slice (that is, with 105 m*M* potassium ions) the narcotic at small concentrations brings about a very large fall in the yield of labelled glutamine, falls in the yields of labelled alanine and aspartic acid and a rise in the yield of labelled glutamic acid These results may be adequately explained on the basis of the conclusions given above, together with the conclusion that the main effect of the narcotic is to suppress the oxidation of reduced diphosphopyridine nucleotide by cytochrome oxidase and its associated phosphorylations

APPOINTMENTS VACANT

APPLICATIONS are invited for the following appointments on or before the dates mentioned

LECTURER or ASSISTANT LECTURER IN PURE MATHEMATICS—The Deputy Registrar, The University, Edgbaston, Birmingham 15 (September 22)

READER or SENIOR LECTURER IN MECHANICAL ENGINEERING at the University of Melbourne, Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W C 1 (October 2)

SENIOR LECTURER or LECTURER IN MATHEMATICAL STATISTICS at, the University of Sydney, Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W C 1 (October 3)

SENIOR LECTURER or LECTURER IN PHARMACY at Rhodes University, Grahamstown, South Africa—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W C 1 (October 15)

SENIOR LECTURER or LECTURER IN STATISTICS at the University of Otago, Dunedin, New Zealand—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W C 1 (October 15)

SENIOR TUTOR-DEMONSTRATOR IN PHYSICS at the University of Sydney, Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W C 1 (Australia, October 17)

SENIOR LECTURER IN ANATOMY at the University of Sydney, Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W C 1 (October 17)

CHAIR OF ELECTRICAL ENGINEERING at the University of Sydney, Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W C 1 (October 21)

LECTURER/SENIOR LECTURER IN BIOCHEMISTRY at the University of New England, Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W C 1 (Australia, October 23)

LECTURER (with a university degree in mechanical engineering and experience of machine-shop practice) IN THE DEPARTMENT OF MECHANICAL ENGINEERING at the University of the Witwatersrand, Johannesburg, South Africa—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W C 1 (October 31)

SENIOR LECTURER (with an honours degree in electrical engineering and postgraduate experience in the fields of electric power) IN ELECTRICAL ENGINEERING at the University of Tasmania, Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W C 1 (October 31)

ASSISTANT LECTURER and DEMONSTRATOR IN PHYSIOLOGY—The Secretary, Queen Elizabeth College, Campden Hill Road, London, W 8

ASSISTANT LECTURER, Grade III, or DEMONSTRATOR IN CHEMICAL PHYSIOLOGY—The Registrar and Secretary, The University, Bristol

DEMONSTRATOR IN BIOCHEMISTRY—The Administrator, Department of Biochemistry, South Parks Road, Oxford

DEMONSTRATOR IN PHYSICAL CHEMISTRY—The Registrar, The University, Nottingham

HEAD (honours graduate) OF THE DEPARTMENT OF GENERAL STUDIES to co-ordinate and extend all existing general studies—The Registrar, College of Technology, Ashley Down, Bristol 7

HEAD (honours graduate, preferably with a research degree, and with good industrial experience) OF THE DEPARTMENT OF MECHANICAL ENGINEERING—The Registrar, College of Technology, Ashley Down, Bristol 7

THE DISCIPLINE OF THE SCIENTIFIC METHOD

THE address, "The Message of Science", which Prof. P. Weiss delivered at the Universal and International Exposition at Brussels on June 25, 1958, and which has now been issued as an Occasional Paper of the Rockefeller Institute, develops three main points. Man's hope lies in the advance of civilization, of which science is a part, and to understand the role of science requires insight into its nature, power and limitations. First, Prof. Weiss argues, man will continue to reap rich fruit from scientific progress. Secondly, understanding the process of science gives man a firmer grounding in reality against his floundering and fumbling in abstractions; and thirdly, the task of science is to serve man by mastering Nature and not to become man's master. In serving man, science, Prof. Weiss urges, must close ranks with other servants of humanity—the creative arts, philosophy, religion—all striving for a new integrated humanism.

In this view, science, which has helped to dethrone man from his self-appropriated station as the centre of the universe, can help him now to grow into his rightful stature. Prof. Weiss's address is thus essentially a contribution to the discussion on the place of the universities in the scientific revolution which Sir Eric Ashby opened in "Technology and the Academics" and which Sir Charles Snow has developed further in his Rede Lecture, "The Two Cultures and the Scientific Revolution"[*]. Prof. Weiss does not disparage the material benefits which science can provide, but he lays his stress on the contribution which science can offer to man's intellectual and moral advance. It would be a distortion to suggest that he is advocating science for its own sake; but, like Sir Edward Appleton in his presidential address in 1953 to the British Association, he maintains that science itself is one of the great human values.

The power of science, Dr. Weiss points out, comes from the strict mental discipline and critical detachment that it imparts to those who live and practise by its code; and if living by this code can help men to lead more satisfying lives, so as more fully to enjoy and share promised release from want and drudgery; if science will not just extend man's span of life but also give the content of that span more purpose; if science can convince man that many of the evils and errors and convulsions of the present age arise from his ignorance and neglect of the very code of science; then science will have given him another noble gift, namely, a basis for responsible and judicious self-direction as a design for living. This presupposes that man is free to choose his course for better or for worse, and in this choice, the scientific approach can help him to avoid predictably disastrous turns and missteps. Science is not to blame for man's misdirecting scientific knowledge to evil ends.

If the scientific spirit can teach man reason, the message of science must, however, first be accepted by man, and it is Sir Charles Snow's contention that one of the two cultures he predicates as existing does not and will not accept that message. First, however, the characteristics which Dr. Weiss describes as marking the scientific spirit as superior to the mere application of logic, the Golden Rule, or just plain common sense should be noted. It is the categorical demand for validation and verification of each premise, each contention and each conclusion by the most rigorous and critical tests of evidence. Every rule and law have to be tested and enforced, and nowhere else is the penalty for error or infringement so prompt and telling.

This discipline of the scientific method, broadly applied, could go far toward clearing the underbrush of superstition and prejudice that hampers civilization in its march, but it has its limitations. Since, according to the code of science, no positive assertions are final and all propositions approximations, and indeed provisional, science is seen to advance more by denying what is wrong than by asserting what is right—by reducing, and eventually eradicating, errors rather than by heading straight toward some preconceived final truth. From any point along the frontier of knowledge which mankind faces, the imagination and curiosity of individuals may start tracks that radiate in all directions into the unknown. Through trial and error the right path is gradually singled out from the multitude of blind alleys by the fact that it has met, instead of missing, other new or familiar lines starting from other points, merging with them in mutual reinforcement. Success lies in the confluence of thoughts from many diverse directions, and this gives science its coherence and consistency, with a stable inter-convertible currency of terms and units, modes of operation and standards of proof or disproof, all gained by gradually removing the inconsistencies and incongruities within the system, by the systematic reduction of margins for error.

Dr. Weiss points out that this is the method of organic evolution, but on the infinitely faster scale of thought processes, which require much less time to establish their soundness; and from this comes man's unprecedented chance for rapid progress—from the incessant weeding out of error. Moreover, for science as a whole, truth is that strip of possibilities left over after all demonstrable untruths have been eliminated; there will remain a fairly broad band of uncertainty, including the indeterminate, the unknown, the indeterminable and the unknowable The limits of science are frankly acknowledged, and Dr Weiss has no place for either the shallow optimism that Sir Charles Snow marked as contributing to the divergence of the two cultures he describes, or for the uncritical claim that science is a cure for all the ills of mankind and that it can prescribe ultimate goals to guide man's conduct On the contrary, the humility and courage required to live with partial answers and the disturbance of complacency should assist science—and the scientist —to live with the other claimants to a share in human destiny. The scientific spirit, by stimulating man afresh to search and strive again rather than to conform, to face problems and not to accept past solutions, and to exercise ingenuity instead of abdicating to authority, could rekindle flames which mechanization threatens to extinguish

---

[*] The Two Cultures and the Scientific Revolution. By Sir Charles Snow. (The Rede Lecture, 1959.) Pp. iv+52. (Cambridge: At the University Press, 1959.) 3s. 6d. net.

Dr Weiss's view of the relations of science with the creative arts, with philosophy, with at least the kernel of religions (not of creeds) and with the lessons taught by history, all of which are companions with science in shaping the fate of mankind, presupposes, however, a bridge rather than the gulf which leads Sir Charles Snow to speak of the two cultures—it invokes comprehension rather than incomprehension on both sides If the attitude which he depicts should prevent the scientist from contributing to misunderstanding or stirring up resentment, there must none the less be understanding and not prejudice on the other side It will not suffice for science to be objective, to recognize soberly its own limits, and to claim no greater share of man's allegiance than it can ask on scientific grounds It can scarcely act as educator unless there is sympathy and receptiveness on the other side That must precede the abatement of suspicion and resentment, the removal of barriers due to prejudice and the disappearance of any fears of aggressive expansionism of science

This exposition of the message of science ends with an appeal that men of science should close the ranks with those in other walks of life against the dehumanization of our culture, and that they should look and work for a broad humanism in which science is accepted, not grudgingly but with understanding, by all men in all walks of life, not for its fruits alone but for the ideal of rational thought which it can carry to its highest culmination At the same time, men of science must ever be on their guard against the danger of specialist isolation to the neglect of other human values, and finally Dr. Weiss pleads that science should re-acclaim diversity as the source of progress, including the diversity of human minds in their responsible expression Simultaneously, he pleads that those humanists who are not scientists should not regard themselves as the prime custodians of civilization, shunning science as if it were inhuman.

The conception of the message of science and the place of the scientist in our civilization which Dr Weiss expounds in this address is dignified and noble as well as restrained, it could well elicit the response he seeks from the non-scientists if it can reach them But while Dr Weiss recognizes as clearly as Sir Charles Snow the gap between the two cultures and the imperative need for co-operation between scientist and non-scientist, he does not indicate how the gap is to be bridged It is true that, if his counsel is followed, scientists could do a good deal to remove the prejudices and suspicions which have enlarged the gap—or at least to remove the substance of those prejudices and suspicions, but something more is required to restore unity to the intellectual life of Western society, or even to provide a meeting place for the two cultures The lack of comprehension of science and technology on the part of the non-scientist which leads Sir Charles Snow to describe the literary intellectuals as natural Luddites must be removed also, and this as he sees clearly is a problem of education Until intellectuals and the nation generally come to understand the scientific revolution and its implications, Britain cannot hope to cope with the problems offered and either avert the dangers or exploit their possibilities

Sir Charles Snow faces this question in the last part of his lecture He believes that we need as many outstanding scientists as the country can produce They present no problem, but their number is limited, and they need a much larger number of professional scientists for the supporting research and high-class design and development, here the problem is not so much that of quality as numbers These in turn require a large number of supporting technologists and technicians for the secondary technical jobs, some of whom will take major responsibility, particularly in the human jobs Here our problem is both the numbers required, which will throw an immense strain on the universities, university colleges, colleges of technology and technical colleges of Britain, and the distribution of ability in order that proper and efficient use may be made of their services Lastly, there must be not merely politicians and administrators, but also an entire community knowing enough science to have a sense of what the scientists are doing

Sir Charles offers no prescription as to how all this is to be achieved He simply presents the challenge to the educational system of the country, with the reminder that our real assets in the world to-day are our wits—our capacity for co-operation and our inventive and creative ability The survival of Britain as a world power requires that we should fully understand the scientific revolution, educate ourselves to the limit and give the lead to the world We cannot do this without breaking the existing pattern of education; but unless we do so and educate ourselves adequately, we must experience in our own life-time a steep decline in our standards of living To close the gap between the two cultures is a necessity in the most abstract intellectual sense, as well as in the most practical, in order that we may be able to achieve even the political techniques which will enable us to bring our human capabilities into action Once again we are summoned to look at education in the broadest sense, and Dr Weiss's message is an invaluable contribution to such a task

LATIN IN UNIVERSITY ENTRANCE REQUIREMENTS

THE controversy about compulsory Latin for entrance to Oxford and Cambridge flares up sporadically, like the plague, but it does look as though the recent outbreak may be the last. True, Oxford has reversed its decision to make German and Russian alternatives to Latin, but when the committee at present looking into the qualifications for university entrance reports, it seems likely that some means will be recommended whereby Latin can be avoided.

It is difficult to see what benefit the average boy (or girl) who wants to specialize in science can derive from Latin at Ordinary level in the General Certificate of Education. He will not be able to read the simplest texts with any ease, even if he wanted to, and the feeling among many scientists that Latin is a waste of time makes it very unlikely that he will. His attitude to Latin, which is often crammed in a few months and as quickly forgotten, is one of resigned hostility.

"Without Latin the specialists will become even more specialized" is a favourite argument of the anti-abolitionists, yet very few people wish to abolish it unconditionally. At Oxford the suggestion was that Russian and German should be alternatives, and a scientist with French and German is no more a specialist than one with French and Latin. Besides, there is far more chance that a modern language will be kept up, since even the least materialistically minded can see its usefulness. More and more people go abroad every year, especially school children and university students, and later on the professional scientist will want to read papers in foreign languages. Few are published in Latin.

Three main arguments are advanced by those who wish to see Latin retained besides the one mentioned above.

First, they say that it is the key to the understanding of Western culture. Quite apart from the fact that Latin at Ordinary level is not even a key to the understanding of Latin, in order to 'understand' Western culture one has to know a good deal about it, and, as is so frequently pointed out, most scientists do not—though many are more knowledgeable than is often allowed. Latin is, no doubt, an immense asset to the scholar with a wide knowledge of the literature, philosophy, art and history of Europe and America, but to the scientist it is rather like studying the quantum theory without knowing what radiation and algebra are; or, to take a non-scientific simile, to study the sources of Shakespeare's plays without having read "Hamlet". With an educational system which imposes specialization at the age of fifteen we cannot afford the time for intellectual luxuries. It is the stuff of Western culture that should be studied, not Latin grammar.

Secondly, Latin is said to be a unique training for the mind. This argument is difficult to refute, since it is so vague and is so seldom elaborated. It is significant that it is usually advanced by people whose mental training was largely based on Latin. Furthermore, mathematicians can make a similar claim for mathematics with equal justice. Part of the uniqueness of Latin is said to lie in its being a highly inflected, and so a very precise, language; but so are German and Russian.

Thirdly, Latin is said to improve one's English. Maybe it does, but it is an extraordinarily roundabout way of doing so, and one for which the scientist simply does not have the time.

In fact, Latin tends to defeat the very objects it is meant to attain. It becomes associated with other non-scientific subjects and produces an anti-cultural reflex—Latin is a waste of time, therefore French, history and English are a waste of time. It also takes up valuable hours in school which might be devoted to arts subjects likely to interest the potential scientist. It is not suggested that the time spent on Latin should be given over to more science. A debate held recently in the University of London on the motion "That the Education of our Future Rulers should be primarily in the Sciences rather than the Humanities", where scarcely a speaker from an audience containing many scientists supported the motion, shows how much basic agreement there is that education ought not to become too specialized. In view of this, it is a pity that such an issue should have been made out of the relatively unimportant Latin question.

It is high time that some effort was made towards improving the general, as opposed to the specialized, standards for university entrance. If the Latin dispute does nothing else, it focuses attention on this need. Scientists entering for State scholarships already have to take a general paper in English, but it is a special paper for scientists, and so in a sense it condones the existence of Sir Charles Snow's two cultures, instead of tending to re-unite them. If only the universities would demand from everyone three subjects at Advanced level, one a science and one an arts subject, there would be no need to quibble about trivialities like Ordinary level Latin. Quite apart from the wider knowledge this would bring, scientists and arts men would be working together right up to the time they left school, and this is surely essential if they are not to separate into two groups. It has been suggested that as a consequence there would be a slight lowering of standards in the entrance scholarships, and that the colleges would not accept this. If so, it would be a great pity, but it would be a very small price to pay. Besides, it is illogical to complain about specialization and to object to measures which combat it.

Anyone who wants to see compulsory Latin retained for scientists should sit back and ask himself two questions. What am I trying to achieve? What is the best way of going about it? It is very peculiar reasoning that produces Latin at Ordinary level as an essential part of the final answer. The worthy cause of a wider education is being discredited.

THE LIFE OF FREDERICK SODDY

Pioneer Research on the Atom

The Life Story of Frederick Soddy By Muriel Howorth Pp 352+16 plates. (London New World Publications, 1958) 75*s*

THIS is an uneven and uneasy book The scientist who reads it is likely to be exasperated by its not infrequent confusions and repetitions—and the general reader will almost certainly find its detailed chronology difficult if not impossible to disentangle, although the framework of the story is simple enough It is the life-story of Frederick Soddy, pieced together from his casual remarks, from reluctant replies to leading questions, from more sustained and possibly more spontaneous reminiscence, and from the residue of his papers, by his literary executrix and friend of his later years It is a work of obvious devotion, forcefully and at times movingly written, but it achieves no real synthesis

Readers of this journal will remember Paneth's tribute to Soddy (*Nature*, 180, 1085 , 1957) within the compass of a short article, that was generous, just and discerning, written by an expert in his own field who had known him when he was still active in it Paneth wrote "The duty to clarify his picture is specially incumbent on us, as it is the tragedy of his life that members of the younger generation may know him only as the person who adopted the term 'isotope', and, perhaps, as the author of provocative statements in economics and other fields far remote from science The number of those who knew Soddy in his creative period is dwindling He was gifted in many, perhaps too many, ways He was such a good writer of English prose that it was all too easy for him to give his polemical essays the sting he wished"

Frederick Soddy died on September 22, 1956, in his eightieth year His last contribution to the literature of radioactivity was a letter to *Nature* published on September 3, 1932 His present biographer met him first in January 1953 She had then recently read "The Interpretation of Radium" (1909) and had been so impressed by its philosophy that she had sought out its author At their first meeting she suggested to Soddy that they should "together write the record of his scientific investigations" Within a few days she had his agreement Within two months the preface, at least, to "Atomic Transmutation the Greatest Discovery ever Made" had been written This was to be Volume 1 of the Memoirs Volume 2 was unfinished at Soddy's death Then Major and Mrs Howorth came into possession, through Soddy's will, of "all his original papers, letters, and records" In that way the book now under review had its beginning, its conception replacing that of the half-finished Memoirs "Having these [original papers] as my guide", Mrs Howorth confides in her new preface, "I can now write, with less presumption and more confidence, the story of this remarkable man who was destined to play so great a part in the discovery of one of Nature's phenomena, unique in its potentialities and formidable in its power"

It appears to me necessary to give this brief history of Mrs Howorth's book—essentially in her own words—but having done so I am left with scant space to comment on it further In any event I should require many pages to deal with it in detail I can only indicate its shortcomings and its virtues by further quotation "Later, when the speaker at one of the Royal Society Popular Lectures in Canada fell sick, Professor Cox telephoned Rutherford to take his place and this led to his being accorded a Fellowship of the Royal Society of Canada and eventually to the full London Fellowship in 1903" (p 78) , "Superb chemist that she was Marie Curie had foreseen these events, but it was left to Frederick Soddy to establish each one of them by experiment—natural transmutation, 1901 , disintegration theory, 1902 , displacement law, 1911" (p 93) , "By 1905 it was still not confirmed that the alpha particle was a helium nucleus" (p 114) , "In 1932, Harkins's 'neutron' had been experimentally established by Chadwick Later Chadwick went to study in Germany under Nernst and Rubens " (p 129) , " when Cockcroft and Walton in the Cavendish Laboratory succeeded in 'splitting the atom' Cockcroft alone received the award [of a Nobel prize]" (p 188) , 'What exactly is a beautiful equation ?' I asked [Professor Dirac] 'Is Einstein's little mass-energy equation beautiful ?' 'No, that is not beautiful,' he replied, 'but some equations are very beautiful indeed' (p 257) , "One can say that on Soddy's perception the whole of nuclear science has been built" (p 267) , "The loneliness which such inattention from the scientific world creates is sometimes not easy to bear without resentment It may be also, in the case of Soddy, that the loneliness of his early days returned One could imagine that his mother died three times, once in his infancy, once with the death of his wife, and once on his retirement from academic life" (p 277)

I do not think that the historian of the science of this century will pass over the work and the worth of Frederick Soddy, as he himself found it for a season passed over—or imagined that he found it passed over—in his later years He is assured of the esteem of posterity, without special pleading Mrs Howorth's book contains much that will be of interest to the historian, but her special pleading is likely to pass him by NORMAN FEATHER

GUIDE TO MODERN PHYSICS

Handbook of Physics

Edited by Dr E U Condon and Dr Hugh Odishaw (McGraw-Hill Handbooks) Pp xxvi+1462 (London McGraw-Hill Publishing Company, Ltd , 1958) 194*s*

THIS is a magnificent book It contains about 1,500 pages and weighs nearly 3 kgm , dimensions which are achieved by solid packing of authoritative information, with little padding or wordy introductions We have considered it from the points of view both of the senior who has had ample opportunity of forgetting his physics, and of the student who is in the process of acquiring it For both it seems to be an excellent work of reference

It is divided into nine parts mathematics, mechanics of rigid bodies, mechanics of deformable bodies, electricity and magnetism, heat and thermodynamics, optics, atomic physics, solid state, and nuclear physics Each part is divided into about ten chapters, each written by a specialist , there are nearly ninety contributors, practically all from the United States The list of chapters would be too long to enumerate here, but some idea of the contents can be given by saying that the topics are those in which there is considerable interest at the present time. The book gives a general impression of the rapid development of physics in many different directions.

This development has introduced the usual difficulties in keeping the subject-matter up-to-date, and in the preface the editors express some concern about their success. They need not have worried; most physicists would be only too delighted to keep within hailing distance of the amount of physics in this book.

In fact the main criticism of the book is that it does not seem clear about its own purpose. In the preface the editors imply—but do not clearly state—that they regard the contents as "What every physicist ought to know". Surely the claim is outrageous? There can be very few people who have the mental capacity for absorbing all this material; and it is questionable whether such people would best serve physics by spending the time needed for its absorption.

In our opinion, the main purpose of the book is to serve as a work of reference for the expert who has occasion to wander into a field related to his own but unfamiliar to him. He will find the general principles authoritatively and clearly set out, and will be able to see the types of mathematical approaches that are used. He will not usually find experimental details—except for occasional chapters on such subjects as experimental stress analysis, and vacuum technique—since the book is essentially theoretical.

The mathematical part of the book is perhaps the least satisfactory. It contains some elementary material such as logarithms, which seems out of place, and some, such as the theory of probability, which is likely to be of more use to biologists than to physicists; on the other hand, the theory of errors is not treated. Nevertheless, the main content is extremely good and well set out.

The book is beautifully printed and produced, and we have noted only very few misprints and mistakes. Unfortunately, the very high price—which is quite reasonable for the amount of material contained—will probably rule it out for most individual physicists. It should nevertheless be in every library and, more important, every physicist should know of its existence.

REACTION KINETICS

Some Problems in Chemical Kinetics and Reactivity, Vol. I

By N. N. Semenov. Translated by Michael Boudart. Pp. xii+239. (Princeton, N.J.: Princeton University Press; London: Oxford University Press, 1958.) 36s. net.

THIS is the second English translation of the first volume of Prof. Semenov's book on "Some Problems in Chemical Kinetics and Reactivity" to appear in the past few months. Reading it, one is immediately struck by the strength of the author's grasp of the fundamental issues of reaction kinetics, and by his ability to marshal the evidence in a subject where the experimental results are often confused, and their interpretations conflicting.

The volume under review has no pretensions to being a text-book, and is in fact an extended version of an introduction to a symposium held in Moscow; it thereby retains a certain freshness and is notable for the provocative and stimulating points of view which it takes. It begins with a classification and account of reactions of monoradicals (no nonsense about 'what is a radical ?'), a chapter which is to be commended for its discussions on bond energies and the relation of energy of activation to heat of reaction, and for the cautious but telling way in which the relation of structure to reactivity is dealt with. The next section is on competition between monoradical reactions, and here a clear account of the role of peroxides in oxidation of hydrocarbons is to be found; a great deal of modern Russian work of value, much of it unfamiliar to this reviewer, is dealt with here. The mechanism of chain decompositions of hydrocarbons is discussed.

In dealing with diradicals a distinction between the physical concept (triplet state, paramagnetism) and the chemical concept (absence of activation barriers, tending to dimerize, weakness of the second bond) is exemplified at the outset, although there is a general coincidence. The chemical aspects, as would be expected, are stressed.

After this survey, the second (and final) part of the volume deals with chain initiation and termination. This is divided into chapters on dissociation of molecules and recombination of radicals (essentially by homogeneous processes), initiation by ions of variable balance, and the influence of the walls of the reaction vessel. All these are excellent, the last being particularly recommended. It leads to some interesting speculations on the processes of heterogeneous catalysis.

The standard of production of the book is not high, the typescript being rather unsatisfactory, with an irritating and unnecessary symbol for the chlorine atom. The translation is quite good, although marred by a few words like 'organicist', and expressions such as "the 'ion-impact' method imagined by V. L. Tal'roze . . .". For a physical chemist, however, this book of Semenov's should be compulsory reading.

CHEMICAL OCEANOGRAPHY

Apparatus and Methods of Oceanography

By Dr. H. Barnes. Part 1: Chemical. Pp. 341. (London: George Allen and Unwin, Ltd., 1959.) 40s. net.

THE special methods of analysis used in chemical oceanography and marine biology are to be found in a great many different publications, some of which have limited circulations. There is a need for a collection of working methods, preferably with some guidance for the inexperienced. The need is very competently met by this book. Although suitable for the experienced analyst, it is also explicitly intended to help biologists with less chemical knowledge, and to be useful to those with small libraries. The author has therefore devoted the first quarter of the book to three chapters on colour comparators and photometric analysis, to errors and precision, and to the calculation of results. It is difficult to judge the value of this part of the book. It is well done; indeed, it is admirably clear, but much of it seems unnecessarily elementary, and some of the instruments described are surely obsolete.

The rest of the book is very useful indeed. Separate chapters (several for nitrogen and phosphorus) give methods for determination of chlorinity, *p*H, nitrogen, phosphorus, silicon, carbon, oxygen, alkalinity (an account of the carbon dioxide system is interpolated), conservative elements by micro methods, trace metals and plankton pigments. Others describe filtration methods, and sediment analysis. In each chapter, introductory notes explain the application and chemistry of the methods, which are then given tersely in a form easy to follow at the bench. Remarks on matters of technique, interference, and accuracy come last. The methods are well chosen and it is evident that Dr. Barnes is drawing on considerable experience. It is a little surprising that he does not mention the determination of *p*H with indicators, as it is easy to get quite good results with very simple gear. He should be well able to explain and set out the corrections needed for this method, which is still in use.

There are more than 420 references, some 60 of which are in an appendix bringing them up to July 1958. These are invaluable, although there are few from Russian sources. The 45 tables are mostly relevant; but it is not easy to see the need for reciprocals of atomic weights, nor for a complete list of the symbols recommended by the Chemical Society. The index is thorough. The binding and paper seem rather too absorbent for a book which is certain to be used a great deal on the laboratory bench. F. A. J. ARMSTRONG

ATLANTIC HYDROMEDUSAE

The Carlsberg Foundation's Oceanographical Expedition round the World 1928–30 and Previous "Dana" Expeditions

"Dana" Report No. 46: The Hydromedusae of the Atlantic Ocean and Adjacent Waters. By P. L. Kramp. Pp. 283+2 plates. (Copenhagen: Andr. Fred. Høst and Son, 1959.) 60 Danish kr.

THIS work, by one of the world's most knowledgeable experts on the subject, is a valuable addition to the excellent series of *Dana* Reports. It will partly replace and partly help to guide us to the multitudinous works on medusae in so many scattered journals, although it has not a complete literature list.

One might wonder how far this new volume overlaps Russell's monograph on the "Medusae of the British Isles" published in 1953 and if it is necessary or desirable for both to be at hand. That there is considerable overlap is inevitable and as it should be, but the two serve distinct purposes. Russell is confined to British waters—but not as defined by the Convention!—and it has much more detailed descriptions with details of the hydroids and their development where these are known. Kramp covers a much wider field. An example which illustrates this difference is given by the genus *Phialidium*. Russell describes two species but Kramp twelve and four doubtful ones. Kramp's description of *P. hemisphaericum* is contained in ten lines, and Russell's in ten pages.

This new report is in three sections. The first occupies 74 pages and is a systematic account of the species taken on the *Dana* cruise, 1928–30, and in collections made at the request of the *Dana* Committee. Not only are very full taxonomic descriptions given, often clearing up doubtful nomenclature, but also brief but useful summaries of distribution, both geographically and in depth. It contains descriptions of three new species and one new subspecies.

The second section, of more than a hundred pages, is a survey of all the hydromedusae which have up to now been found in the Atlantic and adjacent waters, a term interpreted to include the Caribbean, Davis Strait and Baffin Bay, the Mediterranean, Black Sea and the waters north of European U.S.S.R.: truly a wonderful coverage. This section will be a boon to those struggling with the systematics of medusae as it has a diagnosis of every family, genus and species, and with keys to all species at present considered valid. It makes extensive use of Russell's book and his Plankton Sheets for those species that are given therein, but its wider field will make it a most valuable aid towards the determination of medusae by workers everywhere. The descriptions are concise and their arrangement helps to make them simple to follow. The keys, too, are clear, and if only the medusae themselves were always as clear their determination would be much easier. It is scarcely the author's fault that medusae are so often damaged that in practice the answer to some of the questions may be just a question mark. Because of the changes during development the section is confined to the adult forms. This is a pity because so often the young stages found in the plankton can be puzzling. I was disappointed to see that Kramp had not done more to link the medusae with their hydroids as there is now a great deal of information on this, but he probably considered it to be outside the particular relevance of the book. Doubtful species are mentioned in case future research should point to their validity. In this section, too, their distribution is concisely mentioned.

The third section is for the ecologist and it describes the composition of the fauna of the hydromedusae within each of the zoogeographical regions of the area—the Black Sea excluded—and based on the distribution of the water masses. The number of regions is generous in its coverage, with details separately given for four ecological groups—neritic, slope, oceanic epipelagic and bathypelagic—each being regionally subdivided. The neritic group is given extensive subdivision, first into eight major regions, for example, Arctic, East Atlantic Boreal, etc., and then into provinces, for example, Atlantic coasts of the British Isles, Channel, North Sea, Baltic, Norway north of Bergen, Iceland. Russell, in 1935, laid stress on the value of certain medusae as 'indicator species', and the detail given in this section of Kramp's book will be invaluable in this respect. It is only to be expected that further research will widen our knowledge of the distribution of many of the medusae, and although it is obvious that Kramp realizes this (for example, at the bottom of p. 266), I found some of his statements too dogmatic, and once in error. On page 210 he says that *Ptychogena lactea* is "entirely lacking in the East-Atlantic boreal region". The *Scotia* took this species in the Faroe Channel in June 1958, and indeed Kramp himself confirmed the identification.

Like other *Dana* Reports, the proof-reading and production have been excellent. Those interested in the systematics of medusae or in the ecology of the water masses will certainly want to have this volume, and I have no doubt that their copy will before long be well thumbed. J. H. FRASER

An Anthropologist at Work

Writings of Ruth Benedict By Margaret Mead Pp xxii+583+8 plates (London Martin Secker and Warburg, Ltd , 1959) 42*s*

RUTH BENEDICT and Margaret Mead are two of the best-known names in American anthropology, and certainly the best known to the general public, because their writings have a popular appeal and have appeared in cheap editions This is a book by the second about the first, or rather it is a book about Ruth Benedict and her circle, among whom Margaret Mead was a prominent figure, as she is in the book It contains a number of articles—and also poems—by Ruth Benedict interlarded with introductory pages by Margaret Mead Some of the articles have already appeared in print elsewhere, and the unpublished ones contain so little of scientific interest that it scarcely seems worth while committing them to print , and, indeed, it must be said that much of Ruth Benedict's writing fell into the class of higher journalism rather than into that of scientific anthropology It could, however, be said that it is often helpful in evaluating an anthropologist's writings to have some knowledge of him as a person and of his private interests That would be true, but a brief memoir would have served the purpose better than a book of more than 500 pages and so constructed that the subject of the memoir is constantly interrupted by its editor and the editor by its subject Moreover, even an English anthropologist, who might be expected to find an account of his American colleagues of interest, may find, as I have, the company somewhat dull Those who are not anthropologists will, I fear, find it tedious, for what can be more tedious than the doings and views of persons we have scarcely heard of, and persons of no very great importance ? An answer to that question might be, the revelation of their feuds and personal antipathies Some of the gossip may be true and might be spoken, but it ought not to have been published in print so soon—for example, what is said about the late Prof Radcliffe-Brown , for it is not as though relations between other persons mentioned are treated with complete candour It is a pity that the initial sympathy and admiration which many of us have felt towards Ruth Benedict, an able woman who left some important writings behind her, and also towards the centre of the circle, Franz Boas, should in the course of reading this memorial volume be lost

E E EVANS-PRITCHARD

Nuclear Reactors for Power Generation

Edited by E Openshaw Taylor Pp vii+144 (London George Newnes, Ltd , 1958) 21*s* net

THE basis of this book is a short course of lectures given at the Heriot-Watt College, Edinburgh The first and the final chapters provide a reasonable survey of the application of nuclear power The first of these chapters deals with the world energy requirement, and the importance of nuclear power to the United Kingdom, the United States, the U S S R , and the remainder of Europe The final chapter considers the economic application of nuclear power, dealing with the choice of steam cycle, fuel burn-up and the importance of a high load factor In this latter context pumped storage schemes are discussed

The five intermediate chapters provide a short technical survey aimed at providing engineers concerned with the construction and operation of nuclear power plants with a background of information The text is not intended for the designer The chapter on materials is the exception, however, and is more detailed Certainly the designer would find it a useful survey of the likely reactor materials The potential reactor operator would probably advocate more space being allowed for safety and instrumentation, to enable the control systems of the current electricity authorities' nuclear power stations to be described in detail

A considerable training programme for technicians and operators will be necessary as the large nuclear power stations begin to be commissioned from 1960 onwards This book provides a summary of a typical course

R VAUX

Disposal of Radioactive Waste

By K Saddington and W L Templeton Pp x+102 +8 plates (London George Newnes, Ltd , 1958) 17*s* 6*d* net

THE disposal of radioactive waste material is a problem which had to be faced when the production of radioisotopes commenced on a large scale both in Great Britain and elsewhere It will, of course, become of increasing importance as the atomic energy power programme expands and the use of radioactive material increases in industry and the medical fields

The authors have provided a book which should do much to enlighten the general reader and, at the same time, act as a useful work of reference for those working in the field of atomic energy

Although it is claimed that the book is designed to assist sanitary engineers, the main emphasis is on the wastes arising at reactor stations and fuel-processing establishments A more detailed account of the problems arising in industry would have been an advantage

The important biological aspects are described very fully, perhaps too fully, having in mind the class of reader for whom the book is intended Certain of the other chapters could have been expanded to provide more guidance to those outside the U K Atomic Energy Authority

It is quite impossible in a book of this size to give a comprehensive account of all the problems and their solutions Nevertheless, the authors are to be congratulated on a good attempt to provide a general survey of the disposal of radioactive wastes

Selections from Modern Abstract Algebra

By Richard V Andree Pp xii+212 (London Constable and Co , Ltd , 1958) 42*s* net

A BETTER title for this book might be "An Easy Introduction to some Ideas in Modern Abstract Algebra" It is often said that abstract algebra demands little manipulative technique but a considerable degree of mathematical maturity , the object of this book is to enable the novice to acquire that maturity, starting from little more than basic notions about integers and real and complex numbers The early chapters discuss logical ideas and concepts such as equivalence classes and congruence in detail, with plenty of illustrations and exercises chosen over a wide field , explanations are full and generally careful, though the reader may be left in doubt on whether a postulate is or is not the same thing as an axiom (p 11), and the description of a series as "convergent, perhaps finite" (p 24) is unfortunate.

Boolean algebra receives adequate discussion, with examples from logical puzzles and circuit theory

Groups, matrices, determinants fields, rings and ideals are then brought in at a gentle pace, with a wealth of concrete illustration The author does not disdain to exhibit a diagram of the inter-relations of fields, integral domains, commutative rings, rings, which should help the beginner in the rather tiresome task of remembering the connexions and differences of these concepts The Cayley–Hamilton theorem for matrices is proved, and in dealing with groups the reader is led to see the importance of the Jordan–Holder theorem, though the proof is omitted

The author tells us that the lecture courses on which this book is based have been increasingly popular in the University of Oklahoma, and that engineering students have found the work on Boolean algebra and matrices valuable and stimulating One can readily believe this, for the style is easy and informal, most readers will be keen to go further, and for them the carefully selected references to more advanced works will be useful T A A Broadbent

The Terpenes

By the late Sir John Simonsen and Dr W C J Ross Vol 5 The Triterpenes and their Derivatives —Hydroxy Acids, Hydroxy Lactones, Hydroxyaldehydo Acids, Hydroxyketo Acids and the Stereochemistry of the Triterpenes With Addenda to Volume 3 by the late Sir John Simonsen and Dr P de Mayo Pp ix+662 (Cambridge At the University Press, 1957) 84*s* net

VOLUME 5 of this well-known series contains a comprehensive summary, up to about 1954, of work on the subjects named in the title A few references and rather more ideas date to about 1956 An important section is concerned with the classical stereochemistry of the various then known triterpene skeletons, with some consideration of conformational questions As in previous volumes, conformational formulae are inadequately used, but the volume marks a distinct improvement in this respect There is a considerable addendum bringing up to 1956 work on configuration and structure in the sesquiterpene and diterpene series

Inevitably in a rapidly moving field the book is seriously out of date For example, a number of structures quoted have been superseded and many others then unknown have since been determined There is, inevitably, no consideration of important recent methods such as rotational dispersion, but a rather full account of the use of molecular rotation differences However, it can form a starting point for the research worker and provides some useful summaries of more classical aspects of the subject for teaching purposes A J Birch

Carbon Dioxide in Water, in Wine, in Beer and in other Beverages

By F Justin Miller Pp 49 (Oakland, Calif F Justin Miller, 3166 Birdsall Avenue, 1958) 15 00 dollars

THIS memoir comprises three almost independent essays on (*a*) a numerical method of representing the gas pressure relationships in various carbonated beverages, (*b*) the rate at which such beverages become impregnated by the gas, and (*c*) the rate at which the gas is lost from the carbonated liquids under various conditions No radically new conceptions are developed but numerous graphical and tabulated data are included and the discussion covers many vexed questions such as the role of nuclei and agitation in the effervescence of carbonated drinks and the suggestion, not supported in the present thesis, that various forms of bonding of carbon dioxide, for example, to proteins or as "carbonic acid", play a part Some readers may find the presentation rather verbose and obscure and may feel somewhat perplexed by the description of numerous 'experiments' where it is not always easy to appreciate either the objects or the results Furthermore some at least of the ideas will be provocative as, for example, the view that solutions of carbon dioxide in aqueous liquids may be regarded as dispersed systems similar to emulsions It is further suggested that increasing the level of disturbance during carbonation results in a coarser 'emulsion' so that the gas is entrapped in comparatively large aggregates which are unstable and tend to give rise to over-foaming ('wildness' or 'gushing') when the pressure is released While this view may help in describing the phenomenon of gushing, it leaves out of account much that is known from scientific experiment about this behaviour and moreover does not in any material way contribute towards means of controlling or avoiding the defect As this is only one example illustrating the general character of this monograph it will be clear that the latter makes no claim to be comprehensive, but, nevertheless, it contains a good deal of interest to the physical chemist as well as much that will be stimulating to the more technical reader A H Cook

Animal Behaviour

By Dr John Paul Scott (The College Library of Biological Sciences) Pp xi+281+16 plates (Chicago, Ill University of Chicago Press, London Cambridge University Press, 1958) 37*s* 6*d* net

THE particular value of this book is that it is comprehensible to reasonably intelligent people who have not steeped themselves in the jargon of the ethologists It may be used as a text-book because it covers well the general field of animal behaviour, especially in basic social aspects, but the book is also an introduction which will subtly draw the student forward into a wider range of reading The scientific discipline throughout is commendable

Animal behaviour is concerned with the activity of the whole organism and groups of organisms what an animal is doing is as important as what it is, and behaviour is one of the central problems of existence Dr Scott develops his work from the elements of behaviour, the limitations imposed by anatomy, and the internal causations from physiology, to the subject of learning and the effects of experience This is straightforward going with field and laboratory illustration, but when the study of organization of behaviour and social organization is reached Dr Scott becomes an inspiring teacher He is not to be classed with those practitioners in ethology who cannot see wood for trees he becomes a naturalist seeing individuals and populations in their larger environmental setting The problems of developing sociality and social disorganization in relation to ecological factors are well chosen and illustrated and the reader is left wondering—a valuable mental state—about the puzzling field of the gene complex in relation to homœostasy and habitat selection in very slightly different races of animals It is something of an achievement to write so simply without writing down F Fraser Darling

THE TANDEM GENERATORS OF THE UNITED KINGDOM ATOMIC ENERGY AUTHORITY

By K. W. ALLEN and F. A. JULIAN
Atomic Weapons Research Establishment, Aldermaston

W. D. ALLEN and A. E. PYRAH
Atomic Energy Research Establishment, Harwell

AND

J. BLEARS
Metropolitan-Vickers Electrical Co., Ltd., Trafford Park, Manchester

THE electrostatic generator, associated with the name of Robert J. Van de Graaff, has emerged during recent years as one of the principal instruments in nuclear physics in the range 1–6 MeV. Its advantages are those of flexibility and precision. The type of ion accelerated (proton, deuteron, helium-3, etc.) and its energy can be readily varied, while at a given setting the beam energy can be controlled to 0·02 per cent. The principal limitation of the machine is that terminal voltages greater than 6 MV. are difficult to attain, and, until very recently, no electrostatic generator had produced hydrogen ions with energies in excess of 10 MeV. As a result, studies of nuclei using electrostatic generators have been limited to the lighter- and medium-weight elements. With energies of 12–14 MeV., these studies can be extended to the heaviest elements.

The idea of utilizing the principle of charge-changing to obtain doubling of energy in an accelerator is due to W. H. Bennett, who patented the idea about twenty-two years ago. Renewed interest was shown in the proposal following an article written in 1951 by Alvarez[1], who pointed out many of the advantages associated with voltage-doubling, and an important contribution was made by Weinman and Cameron[2], who developed an ion source which yielded 25 μamp. of negative hydrogen ions.

Briefly, the tandem generator[3,4] depends on the voltage multiplication which can be achieved by injecting negative ions into an electrostatic generator in which the stack, instead of being single-ended as in a conventional machine, extends throughout the length of the pressure vessel. The negative ion source is thus at earth potential and outside the pressure vessel, a factor which is of importance, as we shall see below. Negative ions are conveniently formed by the passage of positive ions through gases at velocities corresponding approximately to the velocities of the outer orbital electrons. These conditions favour the formation of negative ions ; at energies of 10 keV., for example, a hydrogen ion beam passing through hydrogen gas can emerge with 2 per cent in the form of H^-. Unwanted particles, such as neutrons and electrons, are removed from the negative ion beam by the action of a weak magnetic field before injection into the electrostatic generator. The beam is then

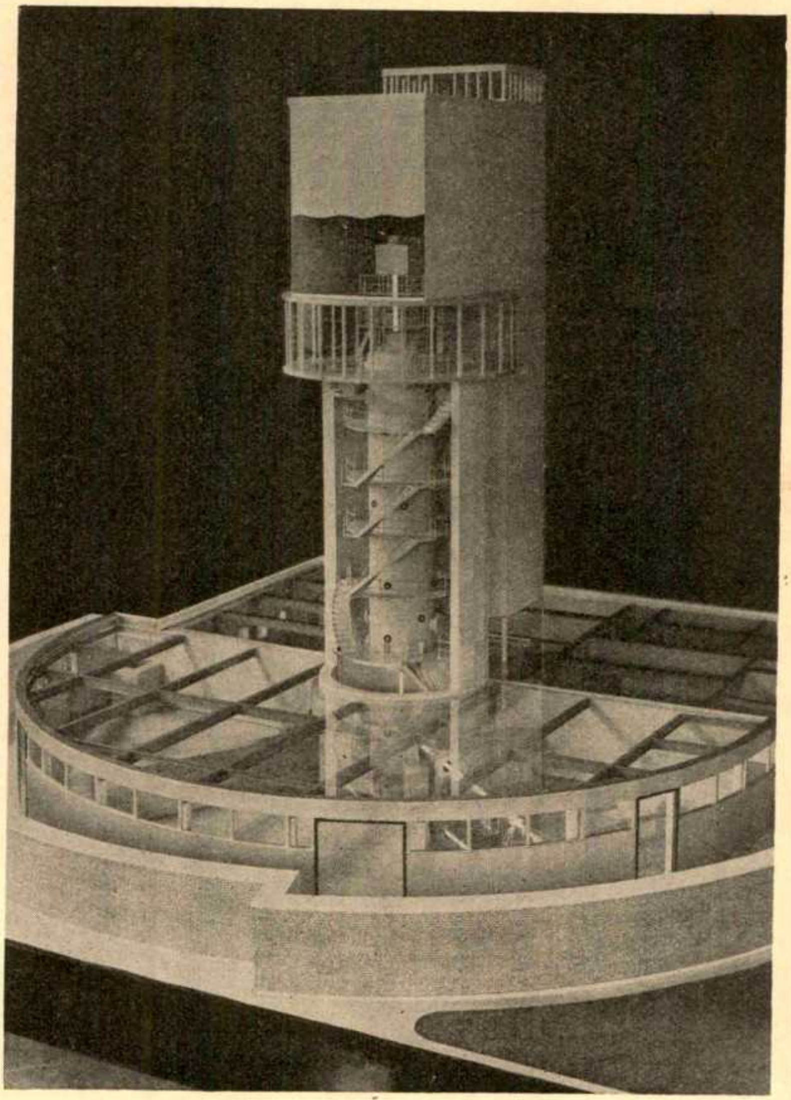

Fig. 1. Model of the tandem generator building at the Atomic Energy Research Establishment, Harwell

accelerated by the positive voltage on the central electrode, and as a result of this acceleration, the ions are moving with a centre of mass velocity large compared with that of the outer electrons about the nucleus. In these circumstances, the passage of the ion beam through a thin foil or tube containing gas at low pressure causes electrons to be stripped off, so that the emergent beam consists of positively charged particles. The energy lost by the beam in passing through the stripper is negligible ($<0{\cdot}5$ keV.). The positive ions are then further accelerated through the second half of the stack. Thus, an H^- ion of charge e, injected into a stack with a central electrode of V volts, will emerge with energy of $2\,Ve$ electron volts. Oxygen ions which are injected as O^- and lose, for example, five electrons at the central electrode will finally emerge with an energy $6\,Ve$, and so on.

The tandem generator has many possibilities. Proton and deuteron beams with energies of ~12 MeV. and oxygen ions with energies of 30–40 MeV. can readily be obtained. In the more distant future, ion beams of helium, lithium, fluorine and any other element capable of forming negative ions (a criterion which includes about half the periodic table) may be produced. The fact that the ions are generated outside the pressure vessel at or near ground potential means not only that the source of most of the troubles in an electrostatic generator is readily accessible for maintenance, but also that there are virtually no limits to the power consumption, size and complexity of the injector system. Thus, millimicrosecond time of flight techniques, which are important in many experiments, are more readily applied in the tandem generator than in the conventional machines, since deflexion and bunching can be applied to the low-energy beam before injection. Finally, it may be possible in the future to polarize the nuclei of negative ions, and eventually to produce beams of accelerated polarized protons.

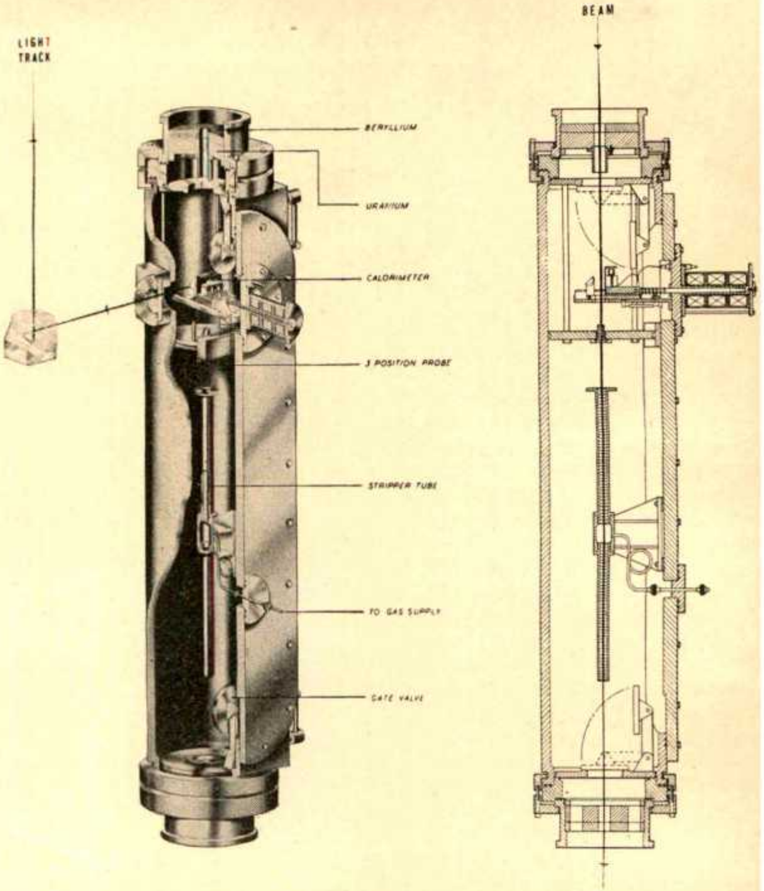

Fig. 2. Arrangement of the gas stripper used to convert negative ions into positive ions in the high-voltage terminal

A horizontal tandem generator has been developed by the High Voltage Engineering Corporation, of Burlington, Massachusetts, for the Chalk River laboratories of Canada, and came into operation in January of this year, following successful trials in Burlington. In 1956 interest in the tandem generator was growing in the United Kingdom Atomic Energy Authority, because the potentialities of the machine as a tool for nuclear research have a direct bearing on the atomic energy programme. Thus, precision studies of the energy-levels of the heaviest elements can for the first time be made with beams of protons or deuterons from the machine; similar studies can be made of the energy-levels and level densities in the region of the periodic table occupied by the fission products. Finally, the availability of high-energy deuteron beams makes possible neutron sources in the region of 8–12 MeV., a region which has hitherto constituted a gap in the energy of neutron sources readily available from conventional machines.

In June 1956, therefore, it was decided to build two machines for the Atomic Energy Authority, one at the Atomic Weapons Research Establishment, Aldermaston, and the other at the Atomic Energy Research Establishment, Harwell. A contract was placed with Metropolitan-Vickers, Ltd., for the engineering components of the British machines; the Atomic Weapons Research Establishment undertook the development of ion sources and strippers, while the provision of accelerating tubes was the responsibility of the Atomic Energy Research Establishment. A vertical design was chosen because there is no experience in Great Britain of the construction of horizontal machines, and it was felt that the engineering difficulties in a vertical machine would be less severe. There are, however, other advantages in a vertical design. In a vertical machine, a much greater weight of equipment can be placed in the centre terminal, so that the possibility presents itself of using the machine as a conventional single-ended machine as well as a tandem. Also, with a vertical machine, the beam can be delivered to any point in a horizontal plane by 90° deflexion in a single rotatable magnet. In Fig. 1 is shown a photograph of the model of the tandem generator at Harwell; the target rooms are disposed in a semi-circle, with two shielding walls dividing the area into three

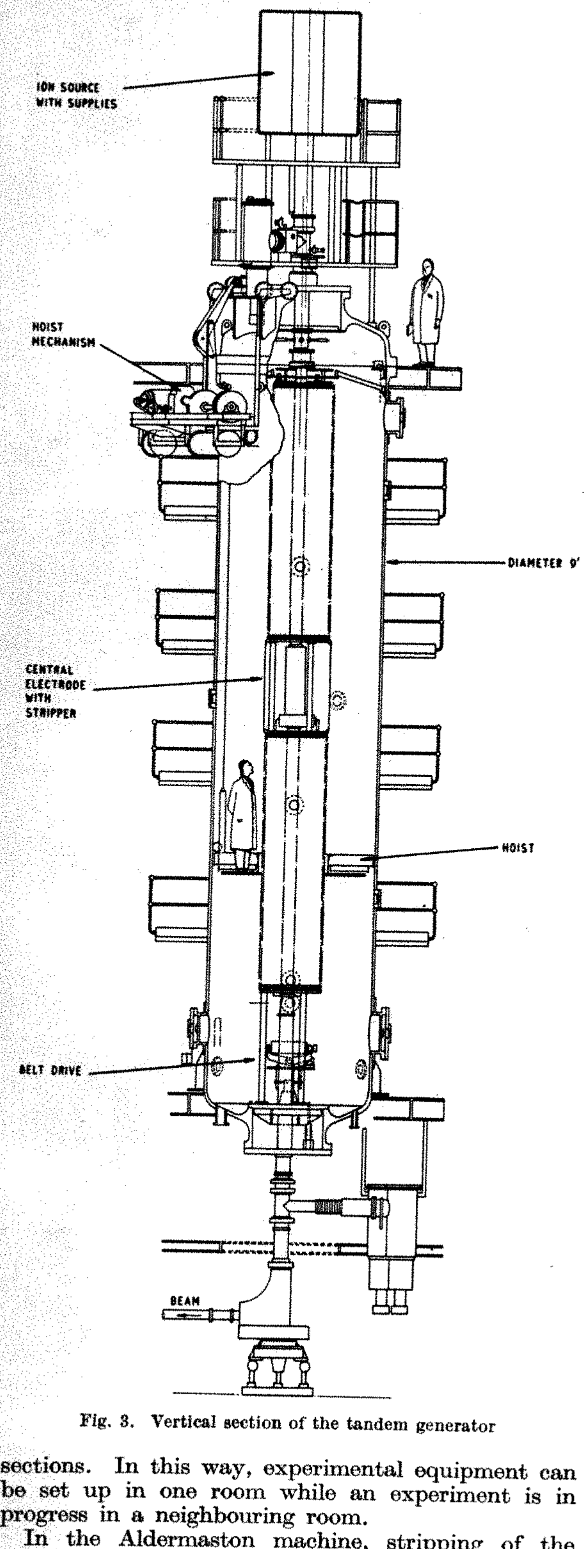

Fig. 3. Vertical section of the tandem generator

sections. In this way, experimental equipment can be set up in one room while an experiment is in progress in a neighbouring room.

In the Aldermaston machine, stripping of the negative ions in the centre terminal is achieved by passing the beam through a tube 24 in. long and 0·14 in. in diameter containing oxygen gas at low pressure. Precise control of the injected beam is required in order to maintain an accurate focus at the centre of the stripper tube for all centre terminal voltages in the operating range of the machine. The advantage of the gas stripper is its indestructibility; however, considerable success has been achieved at Harwell in stripping with thin carbon films 4–5 μgm./cm.[2] thick, and analysed proton beams up to 2 μamp. have been focused on targets. The components of either gas stripper or foil stripper are mounted on a flat plate which forms the greater part of one side of the aluminium alloy chamber (Fig. 2) which joins the two accelerating tubes. The type of stripper or any of its components may therefore be changed at will without affecting the overall alignment of the accelerator.

The injector system, which is described elsewhere[5], is based on a Thonemann ion source used in the manner first suggested by Phillips and Tuck[6]. It is essentially a positive ion source in which electron exchange with neutral atoms takes place in the exit canal. Lens voltages following the canal are reversed, as compared with the typical positive ion source, so that only negative ions emerging from the canal are accelerated. After magnetic analysis to remove electrons and unwanted ions, the ion beam from the source is further accelerated and focused by electrostatic lenses. It enters the first accelerating tube of the main machine with an energy in the range 40–120 keV., depending on the centre terminal voltage. An optical method, suggested by R. Middleton, of observing the beam in the centre terminal has shown that a focus about 3 mm. in diameter can be obtained.

Identical accelerating tubes each 14 ft. long are used in the two halves of the machine. The tubes consist of highly polished aluminium electrodes cemented to accurately ground-glass rings. As in the Chalk River machine[3], the bulk of the gas used in stripping is pumped down the lower accelerating tube. This minimizes the loss of negative ion beam due to charge neutralization in the upper tube.

The engineering of the machine, which will be described elsewhere, is shown in section in Fig. 3. The pressure vessel is 45 ft. long, weighs 45 tons, and when fully pressurized contains about 2 tons weight of nitrogen mixed with carbon dioxide or freon. Access to the machine for general servicing is by the manholes at the base, from which personnel can be hoisted by a lift with driving mechanism situated outside the pressure vessel near the top.

The accelerators at both Establishments have been operating satisfactorily for several months. Proton and deuteron beams with energies up to 11·5 MeV. have been used in experiments, and currents up to 8 μA. at somewhat lower energies are also available.

We wish to express our gratitude to our many colleagues in Harwell, Aldermaston and Metropolitan-Vickers who have contributed to the success of these machines. In particular, we should like to mention A. J. Marriott, J. R. Henry and F. A. Howe of Aldermaston, R. H. V. Dawton and J. H. Partridge of Harwell, and G. W. C. Cogle and J. Roxburgh of Metropolitan-Vickers.

It is also a pleasure to acknowledge the support and encouragement we have received at all times from Sir William Cook and Mr. D. W. Fry, of the Atomic Energy Authority, and the Directors of Metropolitan-Vickers.

UNIVERSITY OF MALAYA IN KUALA LUMPUR

By PROF. R. D. PURCHON
Professor of Zoology, University of Malaya at Singapore

WITHIN less than ten years from its foundation (October 8, 1949) the constitution of the University of Malaya has been radically altered by ordinances enacted by the Governments of the Federation of Malaya and of the Colony of Singapore. The chief purpose of these enactments was to create a new Division of the University at Kuala Lumpur in the Federation of Malaya. The new constitution came into effect on January 15, 1959, and the University now comprises three bodies.

The University of Malaya (chancellor, the Right Hon. Malcolm MacDonald; vice-chancellor, Dr. A. Oppenheim). The main functions of the University of Malaya are the maintenance of co-ordination between the two Divisions, and the conferment of degrees. The authorities are the Court, the Central Council and the Guild of Graduates.

The University of Malaya in Singapore (principal, A. A. Sandosham). The authorities are the Divisional Council and the Divisional Senate. This Division of the University continues to function as before, except for the transfer to the newly created Division at Kuala Lumpur of the Departments of Geology and Engineering and of certain Departments in the Faculty of Arts.

The University of Malaya in Kuala Lumpur (principal, F. Mason). This is similarly administered by a Divisional Council and a Divisional Senate, and is accorded equal status with the establishment in Singapore. This Division comprises Faculties of Arts, Science and Engineering, while the Department of Agriculture will doubtless be accorded the status of a faculty in the space of a few years. The Department of Engineering was transferred as a whole from Singapore a year ago, and is now fully developed in new buildings in the Pantai valley at Kuala Lumpur. The Department of Geology is in the process of moving, only first-year students being taught in Kuala Lumpur during the present session; when the move has been completed, this subject will cease to be taught at Singapore, thus diminishing the diversity of subjects taught in the University of Malaya in Singapore. However disappointing this may be, this rationalization is unavoidable, at least in the early years under the new constitution.

Development of the University site in the Pantai valley at present includes the completed buildings of the Faculty of Engineering, one residential college and an estate of staff houses. Plans are already at an advanced stage for the buildings for the Faculties of Arts and Science and for the Department of Agriculture. Although these buildings will not be completed for a year, students have been enrolled into the 'intermediate year' of the science course and teaching has begun with skeleton staffs in temporary quarters in a local school, the Victoria Institution.

The Asia Foundation has made a most generous offer of help regarding the provision of a nucleus of books for the library at Kuala Lumpur. Consideration is being given by the University authorities to the methods whereby the books and journals in the library at Singapore can be made available to students in Kuala Lumpur, but care must be taken to ensure that the one excellent library is not split into two mediocre ones.

Appointments to the newly created chairs in science subjects are as follows:

Agriculture. The creation of a Faculty of Agriculture at the present time has been made possible by the generosity of the Government of New Zealand, which provided £NZ250,000 specially for this purpose under the Colombo Plan Technical Co-operation Scheme. It is therefore a happy circumstance that the first professor of agriculture should himself be a New Zealander. Prof. G. M. Davies, who was born in Dunedin, graduated at the University of Otago and Massey Agricultural College and then spent a further year at Canterbury Agricultural College. During the Second World War he served with the Royal New Zealand Air Force, and won the Distinguished Flying Cross in 1942. After the War, Mr. Davies worked for three years in New Zealand, first as a farm appraiser with the State Advances Corporation and then as senior lecturer in soils and fertilizers at Massey Agricultural College. In 1948 Mr. Davies moved to the United Kingdom, where he remained for ten years as a regional grassland husbandry officer in the National Agricultural Advisory Service.

Botany. Prof. M. E. D. Poore, the first incumbent of the chair of botany, brings to the newly created Department several years of ecological experience. Graduating from the Botany School at Cambridge, Dr. Poore gained his doctorate in 1954. He studied for a time with Braun-Blanquet in the Montpellier School and then joined the Nature Conservancy at Edinburgh, where he initiated a survey of Scottish mountain vegetation, for which he is well known. He then joined Hunting Technical Services as a consultant ecologist and spent some three years in the Middle East. Here, Dr. Poore surveyed the soils, vegetational units and agriculture of Cyprus, Jordan and Iraq with the view of outlining potentialities for agricultural development in these countries.

Chemistry. The University of Malaya in Kuala Lumpur is fortunate indeed to have been able to attract Prof. R. A. Robinson to this important appointment. Prof. Robinson graduated at the University of Birmingham, where he was awarded the degree of Ph.D. in 1929, and the degree of D.Sc. in 1936. Dr. Robinson held a Commonwealth Fund Fellowship at the University of Pennsylvania and at Yale University, and then held a Sterling Research Fellowship at Yale. Dr. Robinson had appointments at University College, Exeter, and at Auckland University College until the Second World War. During most of the war years he held a senior post in a Chemical Warfare Department. In 1948 he was appointed to the chair of chemistry at the University of Malaya (in Singapore) and holds that post until he returns from a period of study-leave abroad to take up his new appointment in Kuala Lumpur. During his years at Singapore, Prof. Robinson has served a full tour of duty as dean of science, and has also served for a period as acting vice-chancellor. He will therefore bring to Kuala Lumpur an invaluable store of administrative experience. Prof. Robinson is best known for his research in the field of electrochemistry, and is the author of a standard monograph in this subject.

Geography. Prof. Robert Ho, who has been appointed to the chair of geography in the University of Malaya in Kuala Lumpur, graduated from King's College, London. He was awarded the degree of M.A. in the University of London in 1950. He has studied soil survey at Rothamsted, and soil analysis in the Department of Agriculture at Oxford. He was appointed to the staff of the Department of Geography in the University of Malaya (in Singapore) in 1948 and has been acting head of that Department from 1957 until his present preferment.

Mathematics. The University of Malaya in Kuala Lumpur is fortunate in recruiting Prof. C. J. Eliezer to the chair of mathematics. Prof. Eliezer is of Ceylonese nationality; he graduated from the Department of Mathematics at Cambridge, was awarded the degree of D.Sc. in the University of London, and has occupied the chair of mathematics at the University of Ceylon since 1949. He is a mathematical physicist who is best known for his fundamental research in the field of quantum mechanics. Having served for three years as dean of science in the University of Ceylon, Prof. Eliezer will have much experience to offer in the development of the new Faculty of Science at Kuala Lumpur.

Zoology. Prof. J. R. Hendrickson, who has been appointed to the chair of zoology, was trained at the University of Arizona and at the University of California at Berkeley, and joined the staff of the University of Malaya (in Singapore) in 1951. He is a vertebrate zoologist with wide experience and with special interests in herpetology and ecology. His study of the biology of the green sea turtle will doubtless become known as a classic example of objectivity in field research under difficult conditions. His practical experience of the fauna of the Malayan jungle will enable him to endow his Department with an appropriate trend in teaching and research, while his fluency in colloquial Malay will make him specially acceptable in this virile and newly emergent country.

CONTINUOUS-FLOW CULTURE OF THE FILAMENTOUS MOULD *PENICILLIUM CHRYSOGENUM* AND THE CONTROL OF ITS MORPHOLOGY

By S. J. PIRT and D. S. CALLOW
Microbiological Research Establishment, Ministry of Supply, Porton

In a recent report[1] we described the application of continuous-flow technique[2] to culture of the mould *Penicillium chrysogenum*, which is used for penicillin production. This technique has now been used by us to elucidate the influence of *p*H value on the morphology of *P. chrysogenum* in submerged culture. The morphology of the mould is considered to be of importance in the process of penicillin production[3]. The role of agitation in determining the morphology of the mould has been stressed by Duckworth and Harris[4] and by Dion, Carilli, Sermonti and Chain[3]; but so far the influence of *p*H value on the morphology has remained unknown. The elucidation of the influence of *p*H value has been made possible by the advent of reliable means for the accurate control of *p*H value in cultures over long periods[5].

Aberrant Forms of Fungi in Submerged Culture

One of the problems of continuous-flow culture which we encountered was that the mycelia of newer strains of the mould (*Wis* 49–133 and *Wis* 54-1255) selected for high penicillin production grew initially in a filamentous form but after a time in continuous culture the pellet form of growth was obtained. The main morphological differences between the filamentous and the pellet types of mycelium can be seen by reference to Figs. 1*a* and 3. The pellet type of mycelium was undesirable because with it steady-state growth, that is, a constant mycelium concentration in continuous culture, could not be maintained, and also its rate of penicillin production was much lower than that of the filamentous form.

Camici, Sermonti and Chain[6] showed that, in batch cultures, the mycelium develops in the pellet form if the inoculum is below a certain size; but in our experiments the inoculum was sufficiently large to ensure that the mould grew in the filamentous form until after the maximum dry-weight concentration was reached.

We found that pellet formation was linked with the production of swollen, distorted, short hyphæ, which mark an aberrant form. Duckworth and Harris[4], in their observations on the production of this aberrant form, included a series of references which emphasized that agitation played a part in the process. The production of short, swollen hyphæ in vigorously agitated cultures of *P. chrysogenum* under penicillin-producing conditions was confirmed by Dion *et al.*[3], who attributed it to mechanical damage caused by the shearing action of stirring.

It does not seem to have been pointed out previously that abnormally short, much-branched, swollen hyphæ similar to those found to be characteristic of agitated cultures of *P. chrysogenum* have also been found to occur in unagitated cultures of fungi under some conditions. Foster[7], in a short review of this aberrant form, gives references to it going as far back as 1857. Pasteur (quoted at length by Foster[7]), Wehmer[8], Frey[9] and Sakamura[10] have reported the production of this aberrant form by *Mucor*, *Penicillium* and *Aspergillus* species. The many different conditions, for example, lack of oxygen or high acidity, considered necessary for the formation of these abnormal cells have been summarized by Foster[7].

In this article we describe how to produce in a vigorously agitated culture of *P. chrysogenum* either the normal, long, thin hyphæ or the short, swollen type, and also how to prevent pellet formation in continuous culture. The importance of control of morphology in continuous-flow cultures and in aeration is discussed.

Continuous-flow Culture Method

Cultures were grown in a continuous-culture apparatus developed from the type described by

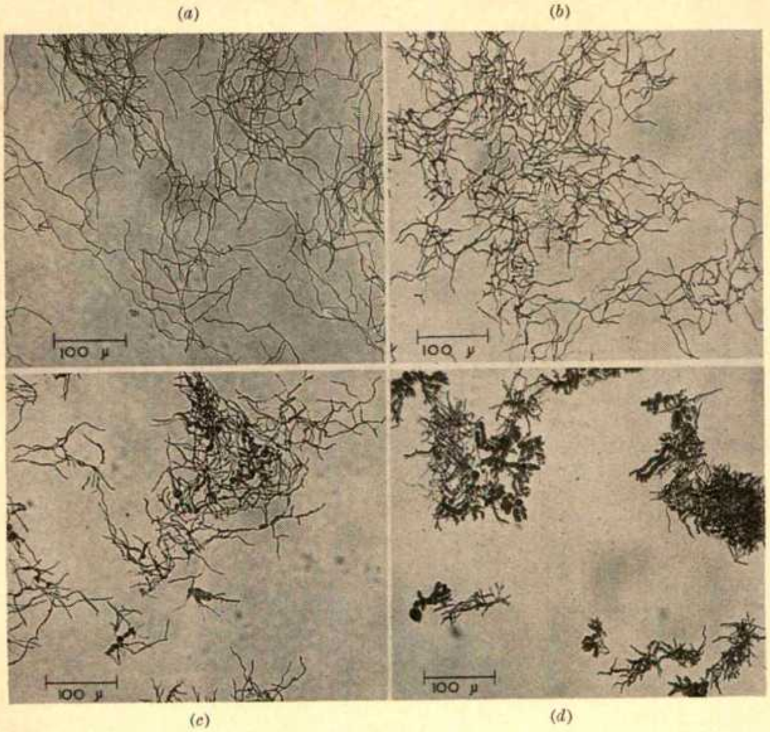

Fig. 1. Mycelial forms of strain *Wis* 54-1255 in cultures grown at different *p*H values. (*a*) *p*H 6·0; (*b*) *p*H 6·5; (*c*) *p*H 6·9; (*d*) *p*H 7·4

Elsworth, Meakin, Pirt and Capell[11]. The *p*H control system was as described by Callow and Pirt[5]. The composition of the medium was (amounts in gm./l.): crystalline magnesium sulphate, 0·25; ferrous sulphate, 0·10; copper sulphate, 0·005; zinc sulphate, 0·02; sodium sulphate, 0·50; manganese sulphate, 0·024; calcium chloride, 0·075; ethylenediamine tetraacetic acid, 0·566; dihydrogen potassium phosphate, 2·0; ammonium sulphate, 6·15; glucose, 20·0; phenylacetic acid, 1·0. The *p*H value was adjusted with sodium hydroxide. In the inoculum culture, which was seeded with spores, phenylacetic acid was excluded from the medium and the glucose concentration was 10 gm./l. Growth was limited by the amount of glucose supplied. There was an excess of available oxygen. Vortex aeration was used with a stirrer speed of 1,200 r.p.m.; the impeller diameter was 0·42 times the vessel diameter; the volume of culture in the vessel was 1·7 l. An antifoam agent ('Alkaterge-*C*' (Commercial Solvents, Terre Haute, U.S.A.) 30 per cent (v/v) in liquid paraffin) was added periodically to the cultures at a rate of 0·1 ml. every hour. The temperature was 25°. The dilution rate (flow rate/culture volume) was 0·05 hr.$^{-1}$, so that the average residence time of the mycelium in the culture was 20 hr. The duration of culture varied from 200 to 2,000 hr. Changes in *p*H value were made at a rate of 0·1 *p*H units/hr. for the reason given elsewhere[12], and where, also, additional details of the continuous-culture method may be found.

The mycelium was stained with cotton blue for the photomicrographs.

Morphological Observations

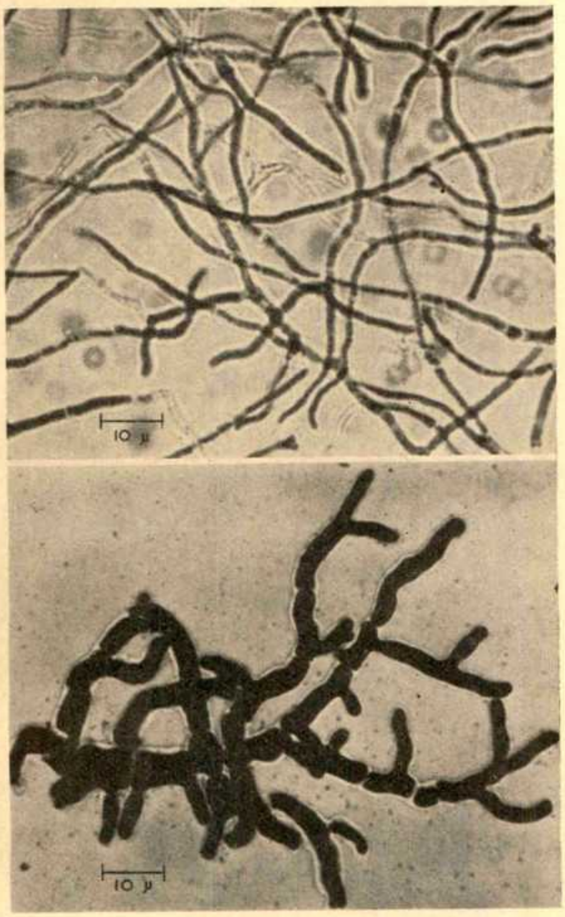
During the initial batchwise growth before flow was started, the mould grew in the filamentous form until the dry-weight concentration was near the maximum, 0·9 per cent (w/v). Then continuous flow was started and the *p*H value, which initially was 7·0, was raised to 7·4 in order to bring it near the optimum for penicillin production. Under these conditions, for about the first 100 hr., steady-state growth was obtained and the dry weight remained at the maximum value. The mycelium form was of the aberrant filamentous type described by Dion *et al.*[3]. The aberrant filamentous form is illustrated in Figs. 2*b*, 4*a* and 1*d*. The characteristics of the aberrant form were the presence of short, much-branched, swollen and often distorted hyphæ. For comparison, the normal filamentous type is shown in Fig. 1*a*. The normal type is characterized by long, thin hyphæ of constant thickness and few branches.

After about 100–200 hr. in continuous-flow culture at *p*H 7·4, strains *Wis* 49–133 and *Wis* 54–1255 began to form pellets of mycelium and gradually, during a further 100 hr., the aberrant filamentous form gave place almost entirely to the pellet form. The initiation of pellet formation seemed to be agglutination of the hyphæ within the individual fragments of mycelium. When the mycelium was completely in the pellet form it sedimented like a suspension of sand grains. The pellets resembled the sclerotic type described by Thirumalachar and Gopalkrishnan[13].

The strains differed in their ability to form pellets. Although all three strains investigated formed the aberrant, filamentous type of mycelium under the conditions stated, strain *Wis* 47-1564, unlike its descendant strains *Wis* 49-133 and *Wis* 54-1255, formed pellets only to a small extent and those that were formed did not persist more than about 100 hr.

We discovered, first with strain *Wis* 47-1564 and confirmed later with strain *Wis* 54-1255, that pellet formation and the formation of the aberrant and normal filamentous forms were determined by the *p*H value of the medium. The influence of *p*H value on the morphology of the mould may be seen in Fig. 1, which shows the appearance of the mycelium grown at *p*H values 6·0, 6·5, 6·9 and 7·4. The average length of branches decreased progressively from the order 200μ at *p*H 6·0 to 20μ at *p*H 7·4. The thickness of hyphæ was 2–3μ at *p*H 6·0, but at 7·4, owing to the formation of swollen cells, the thickness covered the wider range, 2–18μ. Fig. 1*d* shows the large number of swollen, yeast-like cells produced at *p*H 7·4 and also the beginning of pellet formation. Pellet formation was most marked at *p*H 7·4 but it did occur to a lesser extent at *p*H values down to *p*H 6·7 with strain *Wis* 54-1255.

Lengthening of the hyphæ resulted in a marked increase in the viscosity of the culture. The culture produced at *p*H 6·7 and higher values flowed easily like a bacterial culture, whereas the culture grown at *p*H 6·0 had a porridge-like consistency and flowed with difficulty. The dry weights of mycelium in the culture were the same at all *p*H values.



(a)

(b)

Fig. 2. Normal and aberrant types of mycelium of strain *Wis* 47–1564. (*a*) Long thin hyphæ (normal type) produced by growth at *p*H 6·0; (*b*) short hyphæ containing swollen cells (aberrant type) produced by growth at *p*H 7·4

The changes in morphology and viscosity accompanying change in *p*H value were reversed when the *p*H change was reversed, so that, for example, the pellet or short filamentous form gave place to the long filamentous form when the *p*H value was lowered and vice versa. Microscope observations showed that the new form of mycelium produced as a result of a *p*H change arose by new growth from the old form: it was not a transformation of the old form. This was confirmed by the fact that the rate of appearance of the new form was approximately equal to the growth-rate; after a *p*H change it took about three days for the old form to disappear almost completely.

The *p*H value was not the only factor which affected hyphal length and morphology; nutrition also was shown to be a controlling factor. Substitution of the nitrogen source, ammonium sulphate, by corn-steep liquor (filtered, 4·5 per cent (v/v)), which is a common constituent of the media used in penicillin production, increased the hyphal length, reduced the frequency of hyphal branching and prevented the formation of swollen cells at *p*H 7·4. The effect of addition of corn-steep liquor is shown in Fig. 4. These results strongly suggest that corn-steep liquor contains some substance which stimulates the production of the normal morphological type.

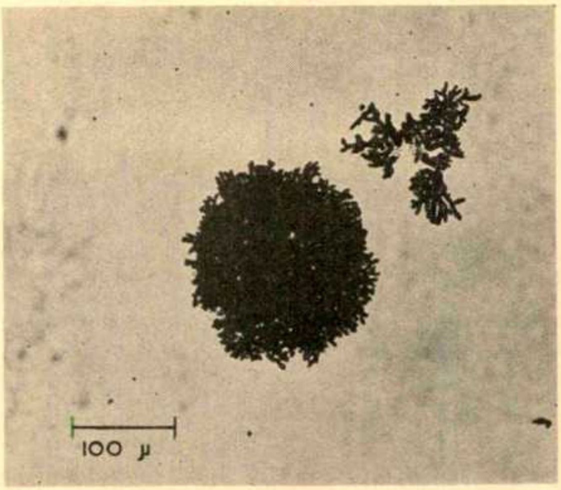


Fig. 3. Pellet mycelium of strain *Wis* 49-133 produced at *p*H 7·4

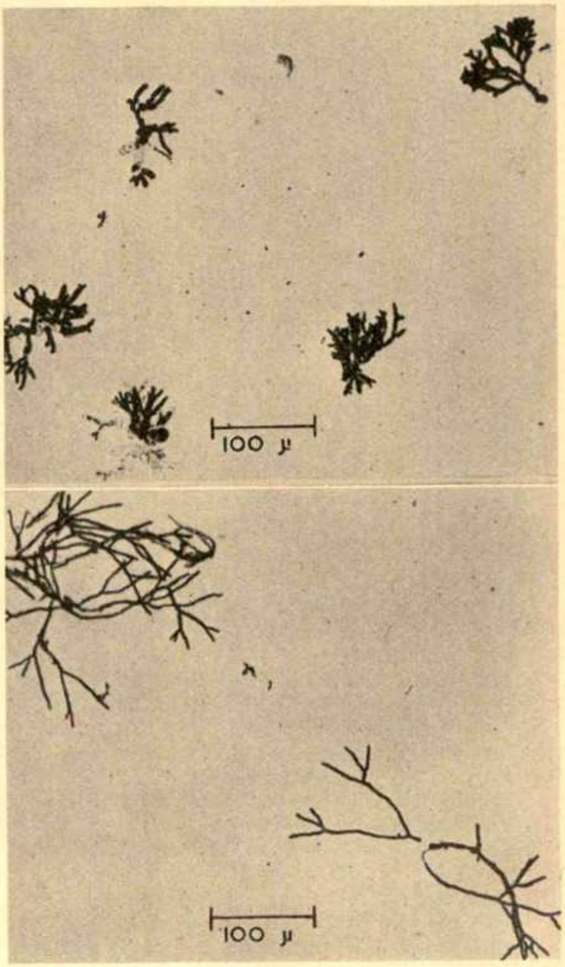

(a)

(b)

Fig. 4. Mycelium of strain *Wis* 49-133 grown at *p*H 7·4. (*a*) With ammonium sulphate as the nitrogen source; (*b*) with corn-steep liquor as nitrogen source

Conclusions: Possible Role of Cell Wall

The conclusions we draw are that: during growth of *P. chrysogenum* in agitated culture the hyphal length decreases with increase in the *p*H value above

6·0; the hyphal length is a minimum at pH 7·0–7·4 and higher values. Extensive formation of swollen cells occurs at pH values above 7·0, this property and the hyphal length being influenced by the medium composition. Pellet formation occurs at pH values above 6·7 but it also shows dependence on strain.

The increase in the length of hyphæ with decrease in pH value we interpret to mean that the resistance of the cells to shear increases with decrease in pH value. We attribute the varying resistance to shear and the production of swollen cells to variation in the cell-wall structure. This idea was suggested to us by the recent bacterial studies which have shown that the mechanical strength of a bacterial cell resides in its cell wall, and by analogy we suppose that the resistance of the fungal cell to mechanical forces is determined by its cell-wall structure. This hypothesis implies that the cell-wall structure or composition depends on the pH of the environment during growth. Also swollen cells could be due to a change in cell-wall structure involving loss of rigidity and consequent inability to resist the internal osmotic pressure.

From the practical point of view the long hyphæ produced at a low pH value are undesirable because they make the viscosity of the culture high and consequently lower the efficiency of mixing and rate of transfer of oxygen[14]. On the other hand, to prevent the extensive formation of pellets and the swollen aberrant form, the pH value during growth should not be greater than 7·0.

Since the optimum pH value for penicillin production is about 7·4 it seems likely that a continuous-flow process for penicillin production will require two stages, the first stage for growth of the mould with the pH value not exceeding 7·0 and a second stage with a higher pH value for penicillin production[15].

We are grateful to Prof. M. P. Backus of the University of Wisconsin for the gift of strain *Wis* 54-1255. Strains *Wis* 47-1564 and *Wis* 49-133 were obtained from the National Collection of Industrial Bacteria, Department of Scientific and Industrial Research, Teddington. The technical assistance of Mr. J. E. D. Stratton is gratefully acknowledged.

TRANSLOCATION OF COBALT-60 AND CÆSIUM-137 BY FUNGI IN AGAR AND SOIL CULTURES

By Dr. ERNA GROSSBARD
Grassland Research Institute, Hurley, Berks
AND
Dr. D. R. STRANKS
School of Chemistry, University of Leeds

A LONG-TERM research project has been initiated at the Grassland Research Institute on the mechanism of microbial decomposition of grass swards after ploughing back into the soil. These investigations comprise, among others, studies on the manner by which saprophytes progress through the soil from one food-base, that is, an aggregate of plant debris, to another. This will be determined by the phase in which the fungus exists in the soil—whether as dormant spores and resting bodies or as an actively growing, progressive mycelium. In this connexion the mechanism of translocation of nutrients by fungi growing in the soil requires elucidation.

Translocation is the movement of nutrients and other materials from one part of the plant to another. As regards higher plants the mechanism of translocation has been studied extensively; but for fungi comparatively little work has been published. Buller[1] investigated protoplasmic streaming in fungi. On the basis of his own work and that of others he concluded that this phenomenon was the principal agent of translocation of nutrients in fungi. Schütte[2], after studying translocation by means of dyes and fluorescein, postulated that fungi can be divided into two groups, translocating and non-translocating, and he, too, associated translocation with protoplasmic streaming. The work of Melin and Nilsson[3,4] and that of Harley and his collaborators[5,6] on the transfer of nutrients into the host by means of mycorrhiza indicates a translocation mechanism via the mycelium.

Preliminary notes have been published by Grossbard and Stranks[7-9] on their attempt to study the growth of soil fungi *in situ* by inoculating soil with a fungal culture labelled with a nuclide emitting gamma-rays. It was hoped that those fungi which produce hyphæ in the soil would form a fresh mycelium growing out from the radioactive inoculum. The new hyphæ would in turn become radioactive and their distribution could be detected by virtue of the gamma radiations which have the power to penetrate the soil. This technique would depend primarily on the translocation of the nuclide from the radioactive inoculum into the new hyphæ, and could provide not only a useful research tool for tracing the growth of fungi in the soil but also help to elucidate the mechanism of transport of nuclides through the soil via fungal hyphæ. This work has been extended and a brief account is given here.

The fungi used in the latest studies were *Pellicularia filamentosa* (Pat.) Rogers (*Rhizoctonia solani*) kindly supplied by Dr. S. D. Garrett ; *Helminthosporium sativum* Pamm, King and Bekke, kindly supplied by Dr. J. H. Western ; *Phycomyces blakesleeanus* Burgeff Herb. Imp. Mycol. Inst. 44142 ; *Phytophthora cactorum* (Leb. and Cohn) Schroet. Herb. Imp. Mycol. Inst. 62471 ; *Rhizopus stolonifer* (Ehrenb. ex. Fr.) Lind. Herb. Imp. Mycol. Inst. 42844.

The nuclides used were cobalt-60 and cæsium-137. They were chosen because they emit γ-photons in addition to β-particles. The fungi were labelled by culturing in media containing the nuclides (1 μc/ml.), which were readily taken up by the mycelium[10]. When grown in broth cultures, 25–50 per cent activity (varying with the conditions of the experiment) could be detected in the total mat after thorough washing.

The main test organisms for the soil cultures were *P. filamentosa* and *R. stolonifer*. Glass tubes filled with sterile soil were used, though occasionally also rectangular boxes. The inoculum for the soil-growth tubes consisted of a number of disks of a radioactive agar culture mixed with soil. This was divided into two halves of approximately equal activity, one of which was killed by heat. Each half was then placed at one end of the soil column in a growth tube. From this inoculum γ-rays were emitted which penetrated the soil. Immediately after incorporation of the radioactive mycelium (living or killed) the tubes were scanned with a directional scintillation counter with a collimator (Ekco model *N* 559*A*). This initial measurement served as a standard to check whether migration of the radioisotope via the fungal mycelium occurred after inoculation and to what extent the radioactive inoculum contributed to the counting-rate as observed at points away from the initial reference source. The figures in Table 1, columns 1 and 3, referring to *P. filamentosa* cultures show that the highest counting-rate outside the wall of the tube was just above the point where the radioactive mycelium had been incorporated. A similar observation was made with *R. stolonifer* and also with *Phytophthora cactorum*. The inoculum of the latter labelled with cobalt-60 was buried several cm. deep in soil in a box and the preliminary scan was performed laterally and longitudinally. In soil-box cultures of *H. sativum* labelled with cæsium-137 the greatest number of counts was also obtained just above the inoculum. This method is useful and can locate with considerable accuracy the position of a radioactive inoculum through soil and the lid and wall of the container.

After inoculation, the growth tubes were incubated and counts were made at weekly intervals. Columns 2 and 4 in Table 1 show the counts after 3 weeks. No significant change in counting-rate could be observed as compared with the first scan. Also the ratio of activity between 'living' and 'dead' inoculum tube was the same after 3 weeks. However, by that time a fresh mycelium had grown out which could be seen to penetrate the entire soil column. This was particularly evident in the *Pellicularia* culture. However, radioactivity could not be detected in this fresh growth. Similar observations were made with the fungi which were inoculated into soil boxes. The failure to detect any radioactivity in the fresh mycelium by scanning with the scintillation counter may have been due to one of three causes. First, the fungi tested lacked the capacity to translocate cobalt-60 or cæsium-137 ; second, the scanning technique with the scintillation counter was inadequate ; and third, the dilution of radioactivity by the outgrowing hyphæ was so great that insufficient activity was produced in the volume being scanned to enable detection.

Table 1. SCANNING RESULTS OF SOIL GROWTH TUBE OF *Pellicularia filamentosa* (Co-60)

Distance from inoculum (cm.)	Counts/sec. Living (1) Initial	Counts/sec. Living (2) After 3 weeks	Counts/sec. Killed (3) Initial	Counts/sec. Killed (4) After 3 weeks
0	800	800	780	780
2	300	320	300	285
4	140	150	145	140
6	90	90	92	84
8	70		66	
10	56	52	55	56
12	46		44	
14	40	39	37	36
20	23		22	
26	16	16	15·5	16·5
32	11·5		12·5	
38	9·5	9·5	9·0	9·6
44	7·4		7·4	
50	6·5	6·6	6·5	6·5

The counts were recorded on a ratemeter Ekco type *N*522 and include background counts of 2·5/sec.

Regarding the first point no information could be found in the literature on whether fungi in general are capable of translocating cobalt-60 or cæsium-137 in a manner similar to that reported for higher plants as regards cæsium-137[11] and cobalt-60[12]. It was therefore necessary to study translocation in fungi in agar and broth cultures.

Beginning these studies with *P. filamentosa* the transport of cobalt-60 from submerged into aerial mycelium was studied by autoradiography employing Pelc's[13] stripping film technique. Cobalt is often considered to be a microbial toxin. However, the addition of cobaltous chloride to the medium—whether as the stable or the radioactive isotope—enhanced the growth of *P. filamentosa*. Details of the experimental technique were described by Grossbard[10], who suggested that accumulation of cobalt-60 occurred inside hyphæ submerged in radioactive agar, for as the autoradiograms showed, the density of silver grains inside the hyphæ was greater than in the agar film between the mycelium. Yet, in autoradiograms of aerial mycelium growing just above the active submerged mycelium the grain density within the aerial hyphæ was similar to that of the background. This suggested that the tracer was not transported into the aerial hyphæ. Similar negative results were obtained from aerial mycelium in broth cultures. It was therefore at first believed that *P. filamentosa* inherently lacked the capacity for transporting cobalt-60 through its system and was one of the group of fungi which—after Schütte[2]—had no translocation mechanism[7,8]. However, when using the stripping film technique very thin preparations have to be made and a few hyphæ only were used. The absence of silver grains in the aerial mycelium may have been due merely to the fact that the dilution of the nuclide when transported from the submerged into the aerial hyphæ was so great that not enough tracer was available for a positive autoradiogram to be formed. That this reasoning was correct was shown when an autoradiogram was produced of large quantities of mycelium placed on an X-ray film. Adapting a technique described by Schütte[2], a small dish of agar containing cobalt-60 was placed

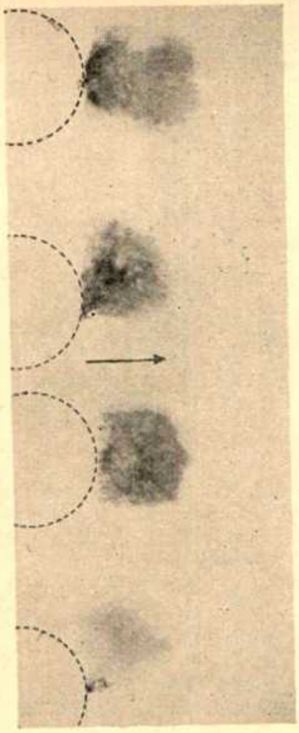

Fig. 1. Autoradiogram of *Pellicularia filamentosa*, 'Cellophane' strips + mycelium

Ↄ Original outline of container (diagrammatic) with agar + cobalt-60 and inoculum of fungus

Arrow indicates inactive agar with fresh mycelium which became labelled with cobalt-60

Gradual decrease in intensity of blackening with increase in distance from active container

inside a large one filled with similar but inactive agar. In the centre of the radioactive dish *P. filamentosa* was inoculated. The mycelium grew out of the dish over the glass edge on to some 'Cellophane' strips situated on top of the inactive agar of the outer container. The strips together with the mycelium were removed and fixed on microscope slides which in turn were placed in close contact with an X-ray film 'Industrial *B*' (Ilford). After exposure for 3 weeks a clear image of the mycelium developed, suggesting translocation of cobalt-60 from the inner container via the mycelium (Fig. 1). The blackening was most intense at the points where the 'Cellophane' strips were nearest to the container with the radioactive agar and decreased in intensity with an increase in distance. However, when tufts of hyphæ were removed from the 'Cellophane' strips at intervals of 5 mm. the resulting autoradiograms were negative. These observations indicate that a translocation mechanism for cobalt-60 and probably other materials does occur in *P. filamentosa* but that it cannot be demonstrated readily in individual hyphæ.

Translocation was then studied in some Phycomycetes, that is, in *R. stolonifer* and *P. blakesleeanus*. These two fungi were grown in flasks with a layer of radioactive agar at the bottom. Individual sporangiophores or tufts were removed and fixed to a glass slide with collodion and autoradiograms prepared. Figs. 2*a* and *b* show the sporangiophores of *P. blakesleeanus* labelled with cæsium-137 and cobalt-60, respectively.

The sporangiophores as well as the sporangia of both fungi displayed considerable grain density giving rise to intense blackening which formed a true image of the morphology of the fungal structures. However, in the sporangia the blackening was far more intense. From these observations it was inferred that the nuclides were readily transported from a food base, frequently 5–6 cm. away, through the sporangiophores and that they accumulated in the sporangia. It is tentatively suggested that the two nuclides were translocated by means of protoplasmic flow. Many workers have reported on this phenomenon in *Rhizopus* and other Phycomycetes and have observed that the direction of the protoplasmic streaming was towards the sporangia in which the protoplasm became concentrated prior to spore formation. The analogy with the movement of cobalt-60 and cæsium-137 is thus apparent. Furthermore, Grossbard[10] reported that where cobalt-60 labelled hyphal fragments of *Phytophthora cactorum* were ruptured, the tracer could be found in the cell content which had oozed out but not in the empty fragments. The fact that the translocation of cobalt-60 could be demonstrated in individual fungal structure far more readily in the aseptate Phycomycetes than in the septate *Pellicularia*, when using a medium with the same activity, provided further support for the hypothesis of transport by protoplasmic flow. Buller[1] has shown that both *R. stolonifer* and *P. filamentosa* displayed protoplasmic streaming, but he postulated that the type of streaming and the rate differed because of the presence of septa in *Pellicularia*. The flow passed only via a single pore in the septum and thus was slowed down, and this may have affected both the rate and efficiency of translocation. It seems likely that cobalt-60 is held firmly by the protoplasm and moves through the fungus only in chemical combination with the protoplasm (by co-ordination of cobalt with the amino functions of proteins, etc.). This fits in with the results of Abelson and Aldous[14], who, working with cobalt-59, showed in the case of *Escherichia coli* that the nuclide was "very tightly bound, within the experimental error no tracer was lost by either the exchange with magnesium or inactive cobalt". They suggested as one alternative a "non-specific, non-metabolic attachment to the proteins and other groups of the organism". Thus, if cobalt-60 is transported through the mycelium it is assumed that it is carried along by the protoplasm as an integral part of it.

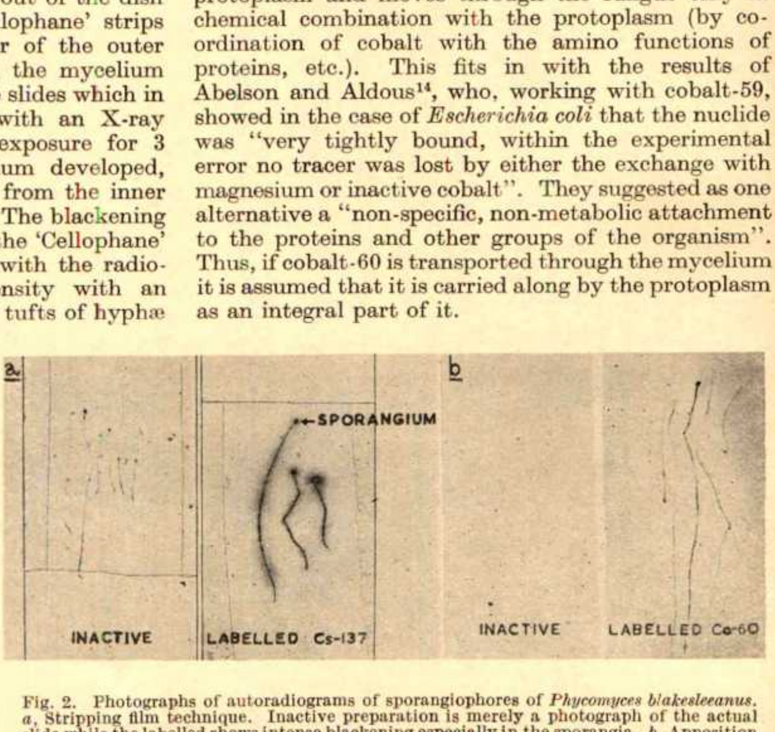

Fig. 2. Photographs of autoradiograms of sporangiophores of *Phycomyces blakesleeanus*. *a*, Stripping film technique. Inactive preparation is merely a photograph of the actual slide while the labelled shows intense blackening especially in the sporangia. *b*, Apposition on X-ray film. Inactive preparation formed no image at all

The above results suggest that all the fungi tested display a translocation mechanism for the two nuclides in agar media, though this is probably more efficient in the case of the Phycomycetes. Failure to detect radioactivity in the new mycelium growing from a labelled inoculum in the soil cannot therefore be explained satisfactorily in terms of an inherent lack of a translocation mechanism in the fungi tested.

While the scanning technique with the scintillation counter could be depended upon to locate a radioactive inoculum in the soil, it may not have been sensitive enough to trace small alterations in the distribution of activity, especially in view of the fact that the strong radiations emitted from the inoculum may obscure any small change in counting-rate due to genuine radioactivity. Having established that both *P. filamentosa* and *R. stolonifer* have the ability to translocate cobalt-60, a more direct method for testing transport via the fungi in the soil was employed. The soil columns after incubation for several weeks were cut into sections of 2 c.c. in the case of *P. filamentosa* and 4 and 6 c.c., respectively, in the case of *R. stolonifer*. Aliquots of 0·5 gm. of soil of each section were extracted with concentrated nitric acid (10 ml.) and the extract counted in a standard *GM*6 liquid Geiger counter tube (Table 2). In addition, a very thin smear was made on a glass slide of 0·5 gm. of very finely ground soil taken from each section, placed on an X-ray film, backed with a 1/16 in. lead sheet and exposed for 3 weeks. Figs. 3*a* and *b* show a representative photograph and corresponding autoradiograms of a preparation and Table 2 summarizes the results.

From both the counts and the autoradiograms, it can be concluded that some slight migration of the nuclide occurred from the soil section containing the inoculum but over a short distance only. This was observed both in the tubes with the killed and living inoculum. Frequently, though not always, movement of cobalt-60 tended to be greater from the killed inoculum. This may be explained in terms of increased permeability of fungal cells after death. As the inocula consisted of disks of agar cultures the nuclide might also have diffused from the agar and not from the fungal structures only. The agar disks were used, because by providing a food base the subsequent growth of the mycelium was greatly enhanced. Other inoculation methods such as by washed mycelium from a broth culture are under investigation in order to eliminate this complication. What migration has taken place may be interpreted on one hand as diffusion of the nuclide from both the agar base and the mycelium and then through the soil, or else as a case of genuine translocation. There is some indication that the migration-rate was somewhat slower in *Pellicularia* than in *Rhizopus*, since in the former activity was rarely found farther than 2 cm. from the inoculum. An analogy with the more efficient translocation mechanism of *Rhizopus* as observed in agar culture suggests itself; but further confirmatory experiments are necessary before drawing final conclusions, for the migration-rate is dependent on many environmental factors, not easily standardized. Whatever the mechanism of the

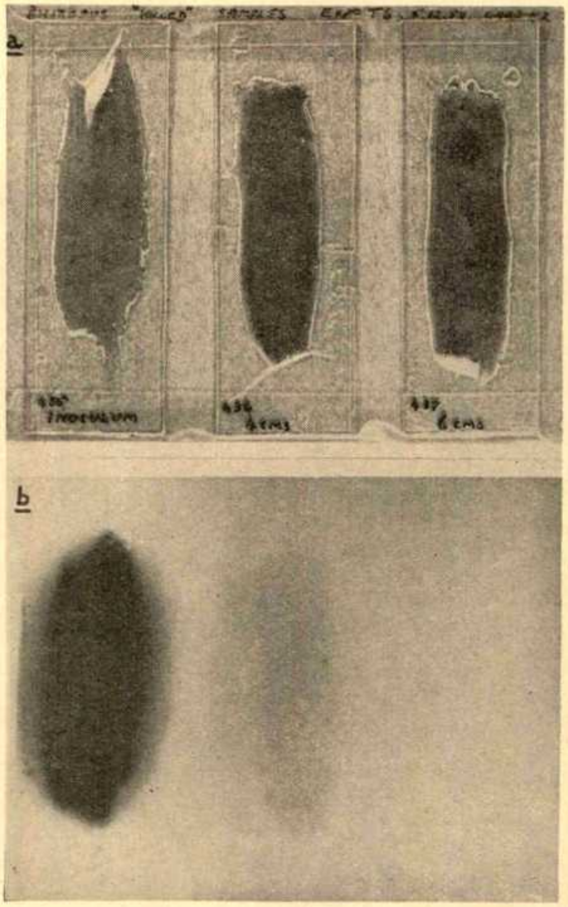

Fig. 3. Photograph (*a*) and autoradiogram (*b*) of soil smears from a soil growth tube of *Rhizopus stolonifer* (killed inoculum, cobalt-60). Soil with inoculum gives the most intense image, a true reproduction of the soil smears. At a distance of 4 cm. the image is much weaker, and at 6 cm. none is formed

migration of cobalt-60 and whatever the difference in rate between killed versus living inoculum or *P. filamentosa* as compared with *R. stolonifer*, the percentage of cobalt-60 and the distance over which it is transported are very small indeed. In every case most of the activity is retained in the section of the soil containing the inoculum. There the nuclide may be held by either adsorption on the soil colloids after having diffused through the cell wall of the fungi or within the hyphæ of the original inoculum, possibly bound to the protoplasm.

Regarding the first point, this would fit in with the observation of Jones *et al.*[15], who have shown that in a soil with moderate exchange capacity cobalt-60 remains close to the surface even after repeated applications of water. These workers placed the cobalt-60 directly in the soil, while in the experiments described here it was introduced via the fungal inoculum ; the soil used was one of moderate exchange capacity.

On the second possibility, Harley and McCready[5] have shown that in the case of excised mycorrhizal roots of the beech 90 per cent of phosphorus-32 absorbed from aerated media was found to be held in the fungal sheath and only 10 per cent diffused into the core. This ratio varied with environmental conditions[6]. By analogy it could be assumed that cobalt-60 also is firmly held within the fungal tissue, especially in view of the observations that migration is of lower order from the living than from the dead inoculum. Thus, the possibility is not ruled out that the small migration which had occurred from living inocula was due to some extent to active transport inside the fungal tissue, perhaps by protoplasmic flow. This is a hypothesis, and more work is required to distinguish between migration by diffusion or by active translocation. Probably both factors will operate simultaneously.

Our thanks are due to Dr. William Davies for his interest in this work, for encouragement and guidance and for providing facilities to carry out these studies. We are indebted to Mr. G. E. Barton for his valuable collaboration and technical assistance, without which this work would not have been possible, and to Mr. D. Smith for the preparation and counting of soil extracts.

OBITUARIES

Prof. Kaj U. Linderstrøm-Lang, For.Mem.R.S.

The death of Prof. Kaj Ulrik Linderstrøm-Lang on May 25 was a great and irreplaceable loss, not only to his colleagues and friends but also the scientific community at large. The Chemical Division of the Carlsberg Laboratory in Copenhagen, which he led with such force and inspiration for twenty-one years, is perhaps unsurpassed in terms of the number of individuals who identify it as a major scientific home.

Linderstrøm-Lang was born in Frederiksberg, Copenhagen, in 1896, the son of Dr. C. F. Linderstrøm-Lang. His education at the Danmarke tekniske Højskole led to a degree in chemical engineering in 1919, following which he became assistant to Prof. S. P. L. Sørensen at the Carlsberg Laboratory. In the environment of Sørensen's fundamental research on the physical chemistry of proteins in solution, Linderstrøm-Lang's natural talents for mathematics and laboratory experimentation led him to conceive in 1925 his classical paper "On the Ionisation of Proteins", which stands to-day as the fundamental theoretical treatment of protein titration curves.

During the period 1926–27 he studied in the laboratory of Prof. R. Willstätter in Munich, and there he developed his continuing interest in the chemistry and mode of action of proteolytic enzymes. Upon his return to Copenhagen he completed his earlier investigations on the electrophoretic properties of proteins and presented his doctoral dissertation in 1929.

His investigations of the nature and determination of proteolytic enzymes, developed in collaboration with the increasing flow of visiting scientists in the Laboratory, became directly applicable to the work he afterwards undertook in collaboration with Dr. Heinz Holter, who went to the Laboratory in 1930. Linderstrøm-Lang and Holter developed, over the succeeding ten years, a tremendous array of delicate and sensitive techniques for the study of the distribution of a large variety of enzymes and other constituents in cells. These micro methods, now standard procedure in many laboratories throughout the world, made possible an enormous advance in our understanding of many aspects of cellular physiology. It is characteristic of the methods that Linderstrøm-Lang developed that they were based on extremely simple but basic physical principles. Well-known examples are the Cartesian diver technique for the measurement of metabolism in single micro-sections of tissue or of individual cells, and the extremely sensitive gradient technique for the determination of the densities of minute quantities of material. A whole generation of young chemists and biologists was strongly influenced by these methods and profited enormously by direct collaboration with Linderstrøm-Lang during this period of his scientific career.

When S. P. L. Sørensen retired in 1938, Linderstrøm-Lang was chosen as director of the Carlsberg Laboratory. Continuing along the lines begun by Sørensen, which had already made the Laboratory world-famous in protein chemistry, Linderstrøm-Lang initiated an outstanding series of studies on the internal structure of protein molecules. Using as probes such phenomena as the volume contraction occurring as a result of proteolytic cleavage of peptide bonds, he began to develop during this period his strong interest in the limited modification of proteins as one means of elucidating internal structure, and published many fundamental papers on such systems as the conversion of chymotrypsinogen to chymotrypsin and ovalbumin to plakalbumin. An example of his inexhaustible ingenuity in the development of experimental techniques was the 'deuterium exchange' technique, which permitted the estimation of the relative rates at which individual hydrogen atoms within the primary, secondary and tertiary structures of a protein molecule could reach equilibration with deuterium atoms in the water in which the samples were dissolved.

Linderstrøm-Lang's scientific talents, combined with his characteristics of warmth and perception, brought him early and frequent recognition by many organizations, both scientific and civic. In addition to receiving numerous honorary degrees from universities throughout the world, he was a member of the Royal Swedish Academy of Sciences, the Academy of Sciences of the U.S.S.R., the Royal Society of London, the Finnish Scientific Society and the National Academy of Sciences of the United States, to mention only a few. He was, at various periods during his life, president of the Danish Academy of Technical Sciences, the Akademiet for de tekniske Videnskaber, and in 1958 of the International Union of Biochemistry.

The list of honours and accomplishments scattered through his career are too numerous to list in detail. Perhaps even more important than these tangibles, however, was the impact of his warm personality on everyone who knew him. Kaj Linderstrøm-Lang had talents in many areas of human endeavour and, had he not chosen science as his major interest, could clearly have contributed prolifically in a variety of pursuits including music, art and literature. Those who knew him will not forget his unique combination of wisdom, humour and intellectual integrity. With his death the world lost not only a great scientist but also a great man.

C. B. ANFINSEN, JUN.

Dr. M. Copisarow

MAURICE COPISAROW who died on April 15, in his seventieth year, was a scientist of quite outstanding ability. His university education was acquired between 1909 and 1913 in the School of Chemistry at Owens College, where I knew him as a fellow student. He stayed on for postgraduate study as Dalton Research Scholar during 1914–16, working with Chaim Weizmann on "Phthalides of the Benzene, Naphthalene and Carbazole Series" (published in 1915). Afterwards, as Honorary Research Fellow (1916–19), he launched out into independent inquiries concerned mainly with reactions promoted by aluminium chloride.

During the First World War, Copisarow worked for the Ministry of Munitions and was responsible for a change in the method of washing TNT which greatly reduced the risk in handling this explosive. At the end of the War he experimented on the conversion of various explosives and also phosgene into products for which industrial uses could be found, and in these operations his eyesight suffered severe injury. Most unhappily, the damage was progressive and in a relatively short time, while still at the outset of his career, he became blind. However, by 1925 he had to his credit nineteen publications of high quality, and in that year he was awarded the D.Sc. of the University of Manchester.

In his work as a chemist he could never have confined himself to narrow specialization. His mind ranged over whole fields of scientific activity, and his keenness of perception allied to his uncommonly active imagination gave rise to a versatility which is well exemplified by his generalized theory of allotropy (*J. Chem. Soc.*, 1921) and by his work on the phenomenon of periodic precipitation, reported between 1927 and 1932 in various scientific journals. These publications illustrate admirably his ability to recognize certain apparently unrelated chemical processes and structures as forms of expression of a unifying principle and to enunciate it.

After he had lost his sight, Dr. Copisarow's scientific activities became restricted principally to the preparation of review articles and essays dealing with matters calling for theoretical consideration. His blindness seemed indeed to intensify his insight, and he extended his thinking to such subjects as the functioning of certain oxidation enzymes, the effects of radiation on enzymes and the biochemistry of virus infection. He studied these matters with the ultimate object of selecting and co-ordinating knowledge which might throw light on problems associated with the malignant growth of cells. Observations on biochemical work in the field of cancer research were published over a period of years in several journals, including a comprehensive review on the "History of Human Cancer", which appeared in the *Edinburgh Medical Journal* in 1952. Copisarow's writings on these matters were prompted by his great desire to contribute all he could to the furtherance of progress in the war on disease.

Further evidence of his feeling for the well-being of his fellow-countrymen is afforded by the interest he had in the application of appropriate scientific knowledge to agricultural pursuits, and during the Second World War he was active in advising on methods for grassland improvement and for the reclamation of bracken-covered areas. In all, he published eighty-three scientific papers, and in recognition of special services to his country he was placed on H.M. Civil List.

Dr. Copisarow was a man dedicated to the work he had chosen, and though, in later years, he had to endure much ill-health and many worries, he remained courageous in adversity, sustained to no small degree by religious faith and by the devotion of his wife and family.

T. K. WALKER

Dr. D. S. Gracie

VOLUNTEERING in the Royal Scots at seventeen, David Smart Gracie was badly wounded on July 1, 1916, at the Somme, and spent the rest of the First World War as a prisoner in Ruhleben, an experience which marked him for life.

In the late 'twenties, after graduating at Edinburgh with a medal, and lecturing on agricultural chemistry, he went to the Colonial Service and carried out a notable "Preliminary Survey of the Soils of Kenya" before the Colonial Agricultural Service had been reconstituted.

Moving to the Egyptian Ministry of Agriculture in 1930, Gracie spent two decades investigating the fascinating problems presented by a soil which has sixty centuries of cultivation history, capped by its change to irrigation all the year round during the past hundred years. As the last survivor within that Ministry in 1949 of what had once been a strong team of some twenty British scientific ex-patriate workers, he finished with a chattering Brunsviga by collating and analysing his results from sixteen continuous years of field experiments on the cotton crop. One side-issue during the Second World War from his work on other crops was to economize tonnage of merchant shipping by showing that imported artificial fertilizers produced much more food for the Egyptian than grain imported as such, which the British army had to bring in for its own use.

In 1949 Gracie started afresh in the dusty precincts of Amman with scanty resources, locating cultivable areas in the Jordan valley and the desert for the United Nations Arab Relief. In 1955 he transferred to Iran with better resources, where he created a large efficient laboratory organization for the United Nations Technical Assistance Board at Teheran. In 1958 he broke down from heat exhaustion, and retired to his Edinburgh home too late, dying there on May 31 of this year, leaving his wife Vera and one son.

With all his work done overseas, in countries not notorious for gratitude, merely increasing the resources of those countries by many acres of cultivation or many more tons of annual crop, he is likely to be one of those for whom there is but little remembrance—a depressing reflexion on those fine political projects for under-developed countries.

Gracie has been described as "a fierce seeker for truth, who could never suffer a rogue gladly", though he might tolerate a fool. He held on to his standards of precision, and made sure that his native assistants did the same.

Out of thirty years joint experience, a mutual friend writes of "the qualities of integrity, judgment, and application in good and indifferent health which he brought to his work. He had none of the narrowness with which specialists are sometimes charged; he was widely read in a diversity of subjects and worth listening to on any of them. Unbending in his uprightness with an inner light which lit for him so clearly the path he held in all affairs, yet he was not stiff; human, kindly, generous, and considerate, his friendship was one of the wholly good things a man could be blessed with". W. Lawrence Balls

Dr. W. W. Francis

Dr. William Willoughby Francis, librarian of the Osler Library at McGill University, Montreal, since 1929, died on August 10, aged eighty-one. A relative of Sir William Osler (his mother was Osler's first cousin, and Osler always spoke of him as a nephew), he was born at Montreal on April 2, 1878, and was educated at Trinity College School, Port Hope, and at Johns Hopkins University, Baltimore, where he graduated A.B. in 1898 and M.D. in 1902. After further study in Montreal, Baltimore, Vienna and London, he returned to Montreal in 1906. In 1912 he was appointed assistant editor of the *Canadian Medical Association Journal* and secretary-treasurer of the Canadian Medical Association, and in 1915 he went overseas with No. 3 Canadian General Hospital (McGill) as registrar. On demobilization in 1919, he lived in Oxford (where Osler was regius professor of medicine) before he became editor of the *International Journal of Public Health* at Geneva.

Dr. Francis's *magnum opus* was started in 1922, when he joined R. H. Hill, Archibald Malloch and Leonard Mackall in compiling the catalogue of Osler's magnificent library at Oxford. Working for 14–16 hr a day for seven years, he succeeded nobly in interpreting Osler's dream of an ideal biobibliography of epoch-making books and in staging it as a pageant. The catalogue under the title "Bibliotheca Osleriana" was published by the Oxford University Press in 1929, and the Osler Library at McGill was officially opened on May 29 of that year. Dr. Francis was president of the Medical Library Association during 1935–37, and honorary consultant to what was then called the Armed Forces Medical Library at Washington.

Bearing a striking resemblance to Osler in the shape of his head, his olive complexion, his dark, humorous eyes, the lightness of his step, and several of his mannerisms, 'Bill' or 'Billy' Francis was a charming man. Someone said of him that he was born under a dancing star and sang his way through life. His learning was vast and bizarre, but never pedantic, his memory was rich and retentive, his humour was spicy and puckish. His seemingly infinite leisure was at the disposal of the young and old who went to him for inspiration and for help. A classical scholar, a painstaking bibliographer ("his meticulosity exceeds anything you ever met with"—Osler), and an unsurpassed writer of whimsical letters, Dr. Francis married in 1921 Hilda Colley, who survives him, with his daughter, Dr. Marian Kelen. W. R. Bett

Prof. A. Preece

The William Cochrane chair of metallurgy in the University of Durham at King's College, Newcastle upon Tyne, became vacant last November with the untimely death of Prof. Archibald Preece at the age of fifty-three.

Preece was educated in South Wales and graduated from University College, Swansea, in 1926. He first joined the Pressed Steel Company of Great Britain as metallurgist, and later became a research officer to the South Wales Siemens Steel Research Association, but he returned to academic work in 1933 when he became a lecturer in metallurgy in the University of Leeds. There he pursued researches on the effect of high temperatures upon steel. The importance of his work was recognized by the award of the Sir Robert Hadfield Medal by the Iron and Steel Institute and by his promotion to a readership in the University of Leeds in 1946.

In 1948 he was appointed to succeed C. E. Pearson as professor of metallurgy in King's College, Newcastle upon Tyne. He took charge of a small but active department of teachers and research workers who carried out important work on the scaling of metals, temper brittleness and the solidification of steel castings, which were Preece's particular interests, though he encouraged others to work on a wide variety of different metallurgical topics. Just before his death he had the satisfaction of moving his Department into more commodious quarters and installing new equipment.

Prof. Preece was a deeply religious man who could be stern or kindly as the occasion demanded. He set himself extremely high standards both in his work and in his dealings with students and colleagues. Probably the most outstanding quality by which he will be remembered was his unwavering integrity and his strict adherence to the truth as he saw it. He was deeply devoted to his work and to his Department, and his sudden death was a great loss to all who came in contact with him.

A. F. Burstall

NEWS and VIEWS

Commonwealth Scientific and Industrial Research Organization

Dr. F. W. G. White, C.B.E.

Dr. F. W. G. White, deputy chairman of the Commonwealth Scientific and Industrial Research Organization, Australia, has been appointed chairman in succession to the late Sir Ian Clunies Ross. Dr. White, who is a New Zealander, went to Australia in 1941 at the invitation of the Commonwealth Government to help in Australia's effort to provide radar equipment for the Australian and United States Forces. When the Organization was formed in 1949 he became chief executive officer, and in 1957 deputy chairman. During the period of reconstruction following the War Dr. White played a leading part in building up the laboratories of C.S.I.R.O., which have since then assisted in the growth of Australia's secondary industries. He was largely responsible for the establishment of laboratories for meteorological physics, coal research and building research. He has been active in sponsoring the formation of industrial research associations and in helping firms to create their own research facilities. Dr. White has taken a direct interest in the development and work of the Organization's laboratories concerned with biological research and has travelled widely to study agricultural and pastoral problems at first hand. Since 1946, when special funds were made available for wool research, he has devoted a considerable effort to the founding and development of the C.S.I.R.O. Wool Research Laboratories, which have done much to sustain wool in the competitive fibre markets of the world.

Dr. White graduated as M.Sc. in 1928 in the University of New Zealand and later went to do research work at the Cavendish Laboratory, Cambridge. He was awarded the Ph.D. degree of the University of Cambridge in 1932. After a period as a University teacher in the University of London, he was appointed professor of physics at Canterbury University College in New Zealand.

Dr. R. N. Robertson

Dr. R. N. Robertson, a distinguished Australian plant physiologist, has been appointed a full-time member of the executive of the Commonwealth Scientific and Industrial Research Organization in succession to Dr. F. W. G. White. Dr. Robertson is an outstanding research worker who has unusually wide interests in both basic and applied aspects of plant physiology. Many of the complex problems facing the farmer and the fruit-grower can only be solved if we know how the plant functions—how it absorbs minerals from the soil and how it uses them to build up its structure. Dr. Robertson has been concerned with these basic problems throughout his career and particularly in his present position as leader of the Plant Physiology Research Unit jointly operated by the Division of Food Preservation and Transport of the Commonwealth Scientific and Industrial Research Organization and the University of Sydney. Work by Dr. Robertson and his colleagues on the growth and development of apples has led to an understanding of the reasons for the poor keeping quality of large fruit and fruit from light crops. His investigations on the maturity of peas have been of particular importance to the vegetable canning and freezing industries. During the Second World War, Dr. Robertson gave valuable help to the food control authorities through his investigations on the causes of heating in stored wheat. Dr. Robertson has spent the past year as visiting professor of horticultural science at the University of California and is at present on a short visit to the University of Cambridge.

Dr. Robertson was born in Melbourne in 1913. He graduated in science with first-class honours in botany at the University of Sydney in 1933 and continued postgraduate research at that University as Linnæan Macleay Fellow. He was awarded a research scholarship of the Royal Commission of the Exhibition of 1851 and went to work at the University of Cambridge, receiving the Ph.D. degree for research in plant physiology. In 1945 he joined the staff of the Division of Food Preservation and Transport of the Commonwealth Scientific and Industrial Organization and took charge of work on the storage of fresh fruit and vegetables. When a Plant Physiology Research Unit was formed in 1952 as a co-operative venture between the Division and the Botany School of the University of Sydney, Dr. Robertson became its leader. Dr. Robertson is a Fellow of the Australian Academy of Science and a corresponding member of the American Society of Plant Physiologists. The Royal Society of New South Wales awarded him its Clark Memorial Medal in 1954. For many years Dr. Robertson was secretary to the Australian National Research Council.

Agricultural Chemistry in Aberystwyth

Prof. R. O. Davies

Prof. Davies has retired from the chair of agricultural chemistry, University College of Wales, Aberystwyth. His services to the University College of Wales and to the agricultural industry of the Principality have extended from 1920 when he was appointed lecturer in agricultural chemistry; in 1939, he became head of the Department of Agricultural Chemistry in the College, which then also served as the agricultural advisory centre for the Mid-Wales area. On the establishment of the National Agricultural Advisory Service in 1946, he relinquished his post as advisory chemist and devoted his activities wholly to College work and to his interests in research.

Prof. Davies has been especially concerned with problems of the nutritive values of lowland and upland swards and of milk composition, particularly in relation to their mineral constituents. His early work with A. L. Provan and W. J. Pugh established that an increase in the protein and mineral constituents of milk occurred when cows were changed from winter rations to lowland pasture. Experimental work on upland swards with W. E. J. Milton (of the Welsh Plant Breeding Station) was begun in 1930; it shows that the mineral deficiencies of these swards can be rectified without resort to ploughing and reseeding. Long-term treatments of upland swards have led to the extinction of the native hill herbage and its replacement by species of high productivity and mineral content, which have become established voluntarily in the favourable environment created through the improvement of soil status and the control of the grazing animal. More recent work with D. I. H. Jones has shown that the mineral content is one factor that influences the nutritive value of the organic nutrients in upland swards, and that the digestibility and the utilization of the digested nutrients of unimproved hill herbage can be increased by feeding calcium carbonate with the grass.

Prof. T. W. Goodwin

PROF. R. O. DAVIES has been succeeded by Dr. T. W. Goodwin, who since 1949 has been senior lecturer in biochemistry in the University of Liverpool. Dr. Goodwin's early work on vitamins A and C has led on to a wide interest in the biosynthesis of carotenoids and in comparative biochemistry; in these fields, the range of his own studies and those in co-operation with other workers has formed the basis of notable developments as well as for a wide series of reviews and contributions to reference texts. He has had considerable opportunities of contacts with overseas research in his own particular and cognate fields of plant biochemistry, having held a Rockefeller Foundation travel grant in 1954, when he worked in the University of California with Profs. Fox and Mackinney, visited many other American universities, and later having taken part in symposia and lectured in several of the leading research centres in European countries. At Liverpool he has been concerned in the presentation of fundamental and applied biochemical principles, not only to honours B.Sc. students but also in the schools of medicine, dentistry and veterinary science. Dr. Goodwin's wide experience in teaching and research will enhance the resources of the Rural Science Departments at Aberystwyth, which, with the closely associated Welsh Plant Breeding Station, have long had special interests in problems of crop, grassland and animal production.

British Gelatine and Glue Research Association: Dr. D. A. Sutton

DR. D. A. SUTTON, chief biochemist of the South African Council for Scientific and Industrial Research Pneumoconiosis Research Unit at the South African Institute of Medical Research, Johannesburg, has been appointed director of research of the British Gelatine and Glue Research Association in succession to Mr. A. G. Ward, who is going to the University of Leeds as professor of leather industries (see *Nature*, 182, 1707; 1958). Dr. Sutton graduated with first-class honours in chemistry at the Imperial College of Science and Technology, London, and after holding posts with the British Rubber Producers' Research Association and the Paint Research Station, went to Pretoria in 1949 where, until 1956, he was head of the Division of Organic Chemistry of the Council for Scientific and Industrial Research, in charge of groups working on various aspects of industrial organic chemistry. He has since been in charge of investigations of the collagen in various living constituents, the chemotherapy of silicosis, and carcinogen liver protein bonding.

Uranium as Fuel

GREAT BRITAIN'S nuclear power programme is based on the Calder Hall type of nuclear reactor which 'burns' natural uranium as fuel. Uranium ore is mined in Australia, South Africa, Canada and the United States and processed to an oxide known as 'yellow cake'. Material from the Commonwealth is shipped to Great Britain and processed at the Springfields factory of the U.K. Atomic Energy Authority into uranium metal and then into fuel elements for British reactors. A special feature of the March 1959 issue of *Atomic World* (10, No. 3) is a series of three articles linked by the theme "From Mine to Fuel Element, 1959", in which the procedure from the initial mining of the uranium ore to the final fabricated fuel element is described. In the first article, "Mining and Processing at the Mary Kathleen", the mining and treatment of the ore to the 'yellow cake' at the recently completed £13 million installation at Mary Kathleen in Australia is considered. This is followed by an account of the processing at the Springfields factory where new plant is being commissioned, and the final article in the series, entitled "Fabricating the Fuel Elements", describes how the billets of natural uranium are cast into rods which are then machined, heat treated and canned in 'Magnox' (an alloy of magnesium and aluminium) to give the fuel elements used at Calder Hall and Chapel Cross. The complete series of operations has been summarized in a composite flowsheet drawn by the staff artist of *Atomic World*. The drawing, 11 in. × 22 in., is very suitable for use in science sixth forms in schools and in technical colleges, and copies may be obtained (price 2*s*. 6*d*.) from the publishers.

Time Ball at Greenwich

AFTER an absence of more than a year, the Time Ball has recently been erected on a new mast on the roof of Flamsteed House, the oldest of the Royal Observatory buildings at Greenwich. A time ball was first erected there in 1833 and it was in 1919 that the aluminium sphere now used was fitted. It was taken down for overhaul in 1958 and as the operating machinery is not yet complete it is not intended to resume daily dropping until the summer of 1960, when Flamsteed House will be opened to the public as an annexe of the National Maritime Museum.

The Ageing Worker

IN a report recently published by the Nuffield Foundation ("Age and the Working Lives of Men: an Attempt to Reduce the Statistical Evidence to Its Practical Shape". Studies of Ageing within the Conditions of Modern Industry. Pp. 68. London: Nuffield Foundation, 1959. 3*s*. net) F. Le Gros Clark, who has been responsible for a number of monographs on ageing, has addressed himself to answering, as best as present evidence permits, the question, what happens within the conditions of modern British industry to ageing men when failing powers make them no longer fully employable on their normal work. He is concerned, that is to say, not with the psycho-physiological aspects of ageing and the changes that take place in the ageing organism, but with the sociological aspects—the fate of ageing individuals in the contemporary industrial milieu. Reliable evidence on this topic is remarkably hard to come by, and Mr. Le Gros Clark has made skilful use of the available statistical data to arrive at his tentative conclusions. Total incapacity for work increases steadily from the age of 55 onwards, and by the age of 65 about 10 per cent of all male workers are totally incapacitated. By the age of 70 this percentage has approximately doubled. The real industrial problem, however, concerns men who are still fit for work, but who because of failing powers need different and less exacting work. At the age of

65 the author estimates that some 20 per cent fall into this category, while a smaller but still considerable number need alternative work well before their mid-sixties There are, of course, wide differences between occupations and the report provides some provisional data relating to thirty occupational groups The Report suggests that an important question is whether an increasingly mechanized industry will be able to provide the kind of work needed by ageing workers and by those who do not wish to retire at 65 If not, what other social arrangements will be needed to ensure the well-being of the ageing man ?

Staff for Industry and Commerce

Two important publications dealing with the control and development of staff in industry and commerce have been issued by the Institute of Personnel Management The first, by E M Barling, late director of personnel of the John Lewis Partnership, is concerned with the management of workers whose skills are mainly mental or social rather than manual Much of the practice described by Miss Barling will be of interest to those dealing with similar problems in large industrial and commercial organizations, Government departments, public corporations, hospitals and scientific establishments The subjects covered include training and education, pay and incentives, consultation and communications, and welfare amenities (Pp 46 London Institute of Personnel Management, 1959 4*s* 6*d*) The second, by F I de la P Garforth, of the Department of Work Study and Staff Training, Engineering and Allied Employers' West of England Association, provides a systematic approach to the provision of supervisors and managers The subjects covered in the broadsheet include organization charts, staff reviews and appraisals, forecasts of vacancies, recruiting policy, further education and training for staff, job rotation and exchange, and a section on the initiation and operation of a systematic management development policy (Management Development a Systematic Approach to the Provision of Supervisors and Managers Pp 72 London Institute of Personnel Management, 1959 15*s* 6*d*)

I C.S.U. Review

THE activities of the International Council of Scientific Unions have greatly expanded during recent years Joint Commissions have been appointed covering fields of interest common to two or more of the constituent unions and other committees have been formed to organize specific programmes of research The recent International Geophysical Year was initiated and sponsored by the Council through a special committee appointed to supervise the programme Despite these outstanding achievements, there is still widespread ignorance concerning the organization and activities of the International Council of Scientific Unions The lack of adequate information concerning its affairs has been felt to be detrimental to the continued growth of the Council As a step towards remedying this state of affairs, and with the view of encouraging the flow of information between individual unions, the Executive Board of the Council has approved the establishment of a new quarterly journal to be called the *I C S U Review*, to provide information to members of the Council and to all who are interested in international co-operation in science, about the activities of the Council and of the scientific unions The *I C S U Review* will contain reports of meetings of the Bureau, the Executive Board, and the General Assembly of the I C S U , information about special activities, reports of some of the more important symposia, reviews of certain publications, special articles on various aspects of international co-operation in science, and announcements about forthcoming meetings, symposia or congresses organized by the unions In the first issue (May 1959 Pp i+56 Subscription 16 florins , 30*s* , or 4 50 dollars per volume of four issues Amsterdam Elsevier Publishing Co , 1959), Prof A von Muralt, treasurer of the International Union of Physiological Sciences and former president of the International Council of Scientific Unions, has written an article entitled "What does ICSU stand for ?" There are other articles on international collaboration in science by L V Berkner, on the International Geophysical Year by Prof Sydney Chapman, on the marine sciences by Roger Revelle, and a review of some aspects of the origins of life considered in the light of the Moscow international symposium of August 1957, by N W Pirie With the increasing importance of international co-operation in science in recent years, and the growing status of the International Council of Scientific Unions as an essential part of the organization of scientific activities on a world-wide scale, the *I C S U Review* will undoubtedly fill an important niche in the literature of science, and will find a place on the shelves of all scientific libraries and information services

Russian Journal of Inorganic Chemistry

A TRANSLATION of the Russian *Zhurnal Neorganicheskoi Khimii*, the only Russian journal devoted exclusively to inorganic chemistry, is being published by the Chemical Society under the title *Russian Journal of Inorganic Chemistry* In an introduction to the first number, the President of the Chemical Society states that it marks a further step in a plan to make Russian chemical literature more generally available Many chemists have become aware of their loss in being unable to read in the original the numerous important scientific papers now being published in the U S S R Although increasing attention is being paid to the teaching of Russian, the need for English translations will inevitably persist for a long time The publication has been made possible by the far-sighted support of the Department of Scientific and Industrial Research The Council of the Chemical Society believes that the venture will not only be of direct value to many research workers, but that it will serve to strengthen still further the sense of international partnership in the advancement of chemical science The translation is by experts The distributors are Cleaver-Hume Press, Ltd , 31 Wright's Lane, London, W 8 The ordinary subscription rate is £30 (90 00 dollars in the United States) per annum, to libraries of universities and technical colleges £22 10*s* (67 50 dollars in the United States), in both cases inclusive of postage The first number has 105 pages in the large format of the *Journal of the Chemical Society* and includes thirty-nine papers and eight brief communications, in all cases in full The topics cover a wide range of interests in inorganic chemistry, some of the papers bordering on physical chemistry, and the standard is high As indicating the general interest of the journal, mention may be made of one paper in which α-MnS is shown to be photo-oxidized during the recording of the powder X-ray pattern, and the published data on α-MnS are wrong

Digest of Soviet Technology

A *Digest of Soviet Technology* is being published each month by Engineering Information Services, Ltd (No 1 , April 1959 8 Victoria Road, Kirkham, Preston) The subscription rate is £6 6*s* annually Such a new digest, with an editorial policy of giving "express information on recent technological developments in the Soviet Union and Eastern Europe", should be of great value to all persons concerned with technical progress in industrial and academic research It is claimed that the information supplied is obtained by critical reading of a large number of periodicals and non-periodical literature published in Soviet countries The fields of coverage are essentially mechanical engineering, production processes and methods instruments and automation The material is divided into the following sections Design and Production , Metallurgy, Welding and Foundry Production , Instruments and Automation , General News, including inventions and book reviews In the third number (June), the editors state that in future greater attention will be paid to 'non-periodicals' This follows when one realizes that a considerable proportion of Soviet technical information is given in books before it appears in periodicals Certainly when this policy is brought into force the *Digest* will be able truly to provide "express information"

Journal of Research of the National Bureau of Standards

It is announced in the April issue of the *Journal of Research of the National Bureau of Standards* that the Journal is now to be published in four separate sections Section *A* (Physics and Chemistry), to be issued bi-monthly, will cover a broad range of physical and chemical research, with major emphasis on standards of physical measurement, fundamental constants, and properties of matter Section *B* (Mathematics and Mathematical Physics), to be issued quarterly, will be devoted to pure and applied mathematics, including mathematical statistics, theory of the design of experiments and numerical analysis , theoretical physics, chemistry and engineering, with emphasis on the mathematical content , and logical design, programming, and computers Section *C* (Engineering and Instrumentation), to be issued quarterly, will include new developments in instrumentation. data processing, test methods, and some of the work in acoustics, applied mechanics, building research and cryogenic engineering Section *D* (Radio Propagation), to be issued bi-monthly, will report research in radio propagation, communications, and upper atmospheric physics The separate sections may be subscribed for individually

British Scientific Instrument Research Association Publications

It is announced in a recent issue of the *Bulletin of the British Instrument Research Association* that several changes are to be made in the regular publications of the Association Henceforth, the *Bulletin*, *Sira Technical News* and *Research Reports*, together with other office matter, are to be printed by the Association For this purpose an office type composing machine (supplied by Vari-Typer Ltd , London) and a Rotaprint rotary printing machine have been installed The type faces used for the *Bulletin* and the *News* will differ from those at present, but the 10-point size will be retained The *Bulletin*, which was originally intended to be circulated to members of the Association only and which now is generally available, contains abstracts from current literature relating to the construction and use of scientific instruments, and news of the Association's activities in a section entitled "Association Notes" However, since March 1953, the second monthly publication, *Sira Technical News*, with a circulation limited to members only, has been issued, the specific aim of which is to tell the members about the Association's work "Association Notes" will therefore, in future, be transferred from the *Bulletin* to *Sira Technical News*, and the title of the *Bulletin* is to be changed to *Instrument Abstracts*

Feltmaking Research

The eleventh annual report of the Director of Research of the British Hat and Allied Feltmakers Research Association for the year ended August 1958 (pp 20 Manchester British Hat and Allied Feltmakers Research Association, 1959) refers to the inclusion of research on finishing processes as a full-time activity Work on the carrotting of furs has shown that the quality of the felt produced is related to the method by which it is obtained and further work has established the importance of body size, weight and build, relative to the size and substance of the hat Work is to start on the stoving of skins in the carrotting process and work on wool noils indicates that only 35 per cent of the overall variability of the felt-quality parameters can be explained by chemical tests for damage Further work was carried out on the determination of the solubility in alcohol of grades of lac, and a study of a new multiroller machine for both settling wool and felting fur bodies indicates that multirollers can be made to give a rapid rate of felting without adversely affecting the quality of the felt, by using a balanced combination of pressure, jig amplitude and frequency, together with a predetermined traverse rate and controlled temperature and acidity A detailed study was made of the technology of a fur-hardening machine as it affects the quality of the hardened forms and hat bodies produced, and in further work on the use of polyethanoxy compounds as dyeing assistants a relation was found between dyeing properties and the partitioning of the dyes into a layer of ethanoxy compound above water dyes with the highest partition coefficients gave the best results on dyeing Studies on frictional properties of felt indicate that frictional behaviour against wood depends on the surface roughness, whereas against phenol-formaldehyde resins, the nature and structure of the fillers are important Work was initiated on the measure of hat felts for tensile properties

The Regional Research Laboratory, Hyderabad

The annual report for 1957–58 of the Regional Research Laboratory, Hyderabad (pp ix + 136 Hyderabad, 1958), emphasizes the further reorientation of the research programme both for team-work and the grouping of schemes into projects For the internal planning and conduct of research the operational research approach has been followed, and this is outlined in the report A striking feature of the year was the increase in pilot-plant work, and particular attention is also directed to the work on 'Citicide', a powerful new insecticide from turpentine developed in the Laboratory , on 'Hykole', active carbons produced from coke , the production of phenylacetic acid and phenylacetamide, for use in the production of penicillin , and on 'Loungimin', a flavouring agent which has twenty times the strength of vanillin Besides brief notes on progress in the various research schemes, arranged under some thirty project headings, the report includes notes on X-ray, instrumentation and physico-chemical studies, analytical work, equipment and machinery, as well as a list of publications and patents, colloquia held during the year, and lists of research staff, Executive Council and Scientific Advisory Committee Somewhat fuller details are given of the castor-oil project, which embraces the refining of the oil, the preparation of triricinolein, using hexane as solvent, the hydrogenation of castor-oil and the preparation of surfactants, the cotton-seed project (including refining, storage, pilot-plant processing and hydrogenation to fatty acids), the fatty acids project, the dehydrated castor-oil project, entomological studies on insecticides, the hand-made paper project, the utilization of the products of low-temperature carbonization of coal (including the preparation of pitch and road tar, preparation of creosotes for wood preservation, recovery of motor spirit, recovery and fractionation of tar acids and their chemical examination) and the glass and ceramics development project

Fencing Posts in Australia

MILLIONS of miles of fences divide and subdivide grazing and farm lands in Australia Their construction, replacement, and maintenance form a major cost item for primary producers A survey carried out a few years ago by the Commonwealth Scientific and Industrial Research Organization Division of Forest Products, with the assistance of the State Departments of Agriculture, gathered essential information on materials, methods, costs, fence-life, and causes of failure of fences on hundreds of farms across the country (Rural Research in C S I R O , 27 Melbourne, March 1959) Much of the cost is in the posts, and years earlier the Division had begun testing small, round, wooden posts to see if they would be suitable After some thirty years trial they proved to be efficient if preserved against decay and insect attack by treatment with creosote An alternative method of treatment using water-soluble preservatives has been developed more recently The Postmaster-General's Department has adopted full-length preservative treatment for its telegraph poles and, as a consequence, expects an average saving of £2 million a year over the next forty years This figure shows the savings that could be made if all farmers used round preserved posts for their fencing requirements Those who are already using such posts have considerably altered their outlook on fencing An important step in reducing fencing costs has been made Other aspects, such as design, have been neglected and appear to offer fruitful fields for research

Inflorescence Inception and Leaf Size in Gramineae

M BORRILL, in a study of the successive leaves on the flowering shoots of *Glyceria*, *Lolium* and *Triticum*, has observed that the blades of successive leaves were progressively longer, eventually reaching a maximum, after which the blades of the last few leaves produced before heading were shorter When the longest leaf blade was elongating, dissection of the shoot apices showed that inflorescence initiation was taking place Epidermal cell measurements in *Triticum* indicate that differences in blade length are due to differences in the amount of cell extension It appears that a correlated change occurs in blade morphology associated with the onset of the reproductive state of the shoot apex, brought about through changes in the amount of cell extension A study of the effect of different amounts of low temperature and different day-lengths on the relation between inflorescence inception and the production of the longest leaf blade showed that, under some conditions, this relation can be disturbed (*Annals of Botany*, N S , 23, 217 (1959))

Belgian Oligocene Foraminifera

THE second of a series of studies on the Belgian Palæogene by a team of micropalæontologists at the University of Utrecht consists of a memoir by D A J Batjes on "Foraminifera of the Oligocene of Belgium" (Institut Royal des Sciences Naturelles de Belgique Mémoire No 143 Pp 188+13 plates Bruxelles 1958) Hitherto very little was known about them, although the Belgian Oligocene includes the type areas of the Tongrian and Rupelian divisions The samples investigated were collected both from surface outcrops and from borings and mineshafts, so that essentially the whole Oligocene was covered Further, some German and Dutch Oligocene and Belgian and German Miocene deposits were examined Altogether some 140 species (of which two are new) are described, all, with the exception of *Nummulites germanicus* (Bornemann), belonging to the smaller foraminifera The author considers that some eight may be index-fossils for the Oligocene, or in any event for the Boom Clay and Septaria-clay One, *Cassidulina carapitana* Hedberg, widely distributed in the Tertiary of the Caribbean-Antillean area, is described for the first time from Europe The faunal assemblages have close affinities for much of Oligocene time with those of north-western Europe and not with those of areas farther south Dr Batjes also made detailed observations on the lithology and lateral variation of the deposits in different parts of Belgium Correlating these with the foraminiferal assemblages, he is led to postulate that parts of the Tongrian and Rupelian deposits are of the same age, and that similar relations may exist between the Rupelian and Chattian

A Reinterpretation of Charnockites

SINCE the publication of Sir Thomas Holland's classic memoir on the charnockite series of peninsular India nearly sixty years ago, similar rocks have been discovered and studied in many parts of the world, and various theories of their origin have been put forward without, however, a thorough knowledge of the type area near Madras from which these rocks were first recorded A detailed re-examination of the rocks of this area has been made by A P Subramaniam (*Amer J Sci* , 257, 321, May 1959) Mineralogical, petrographical, and chemical data are presented which indicate that Holland's "Charnockite Series" in fact contains members which are genetically unrelated to one another Charnockite is re-defined as a hypersthene-quartz-felspar rock with or without garnet, characterized by greenish-blue felspars and greyish-blue quartz The term 'charnockitic suite' is suggested for a group of related alaskites, charnockites (birkremite), enderbites, and hypersthene-quartz syenites, all of which are partly garnetiferous This series corresponds to the "Acid" division of Holland's 'Charnockite Series" The "Intermediate" division of Holland consists of an assemblage of hybrid rocks derived by interaction between charnockite magmas and pyroxene granulites of the basement The "Basic" division of Holland consists principally of pyroxene granulites and interstratified quartzo-felspathic garnetiferous sillimanite gneisses (khondalite), while his "Ultrabasic" division is represented by pyroxenitic schlieren neither the "Basic" nor "Ultrabasic" divisions being related to the charnockite suite The charnockite suite of rocks is considered to be of primary igneous origin, and to have been emplaced as thick sheets and lenses in gently folded basement rocks , all the rock units have later suffered intense regional deformation

Automatic Centrifuge

An eight-page folder issued recently by Ivan Sorvall, Inc , Norwalk, Connecticut, illustrates and describes the super-speed Servall *SS*–3 Automatic Centrifuge and the *SS*–4 Enclosed Centrifuge Both instruments are table-top models with a marked versatility in accepting any one of five different rotors covering a wide range of batch capacities, speeds and gravitational forces After the desired operating speed, running time, and rate of deceleration have been pre-set on the *SS*–3's conveniently angled control panel, the circuit is actuated by the push of a button A particular advantage of the automatic controls is the accuracy with which a given operation may be repeated and complete uniformity of result maintained The *SS*–4 is a manually controlled instrument and the complete control panel is removable for remote operation This is convenient when work demands operation in cold rooms or fume hoods Both centrifuges are designed for rapid adaptation to continuous flow operation with the Servall 'Szent-Gyorgyi and Blum' system, which allows the collection of small amounts of precipitate, in tubes, from gallon quantities of samples

University News . Queen's University of Belfast

The following appointments to lectureships are announced Dr C J M Stirling, organic chemistry , Dr J S Pate, botany , Dr B V Jayawant, electrical engineering , N C Mitchel, geography , W D Ryan, light electrical-engineering

Bristol

The appointment has been announced of Dr W M Shepherd, reader in the University, to the chair of theoretical mechanics The following have been appointed to lectureships P W Bothwell, public health , D R Coles, medicine , D G Osmond, anatomy R Park, civil engineering , N G Sanerkin, pathology

London

The following appointments have been made Prof J L D'Silva, professor of physiology at London Hospital Medical College, to the Halliburton chair of physiology tenable at King's College , A H J Rains, senior lecturer in the University of Birmingham, to the chair of surgery tenable at Charing Cross Hospital Medical School The following have been appointed readers Dr G R Hilson, bacteriology, and Dr D Dexter, morbid anatomy, tenable at St George's Hospital Medical School , J F Smith, morbid anatomy, tenable at University College Hospital Medical School , R E M. Thompson, bacteriology, tenable at the Middlesex Hospital Medical School , Dr P J Grant, engineering science, and Dr B W Martin, applied thermodynamics, tenable at the Imperial College of Science and Technology , E M Rawstron, geography, tenable at Queen Mary College The title of reader in the University of London has been conferred on T E Hughes, zoology, in respect of his post at Birkbeck College , Dr J Wynn Reeves, psychology, in respect of her post at Bedford College , Dr J H Trounce, therapeutics, in respect of his post at Guy's Hospital Medical School

University College of North Staffordshire

The U S Rubber Co has founded a second postgraduate research studentship at the College J Penfold (Nottingham) and J Beard (Southampton) have been appointed to these studentships The Phillips Petroleum Co of Bartlesville, Oklahoma, has founded a postgraduate research studentship at the College, to which C J Panton (Southampton) has been appointed All three research students will work with Dr P H Plesch on problems related to cationic polymerization

Announcements

The Institute of Physics is to hold a conference on Some Aspects of Magnetism during September 22–24 at Sheffield Further information may be obtained from the Secretary, Institute of Physics, 47 Belgrave Square, London, S W 1

An informal Discussion on Flow Properties of Blood and Other Biological Systems, sponsored jointly by the British Society of Rheology and the Colloid and Biophysics sub-Committee of the Faraday Society, will be held in the Department of Physiology, Oxford, during September 23–24 Further information may be obtained from Dr A L Copley, Medical Research Laboratories, Charing Cross Hospital, Strand, London, W C 2, or from Dr G Stainsby, British Gelatine and Glue Research Association, 2a Dalmeny Avenue, London, N 7

A symposium on Depression will be held at the University of Cambridge Post-Graduate Medical School during September 22–26 Information may be obtained from the Secretary, Medical School, Tennis Court Road, Cambridge

The 250th anniversary of the successful use of coke in ironmaking is to be celebrated by a meeting at the University of Birmingham and at Coalbrookdale, Shropshire, during September 23–25 Further information can be obtained from the Secretary, Iron and Steel Institute, 4 Grosvenor Gardens, London, S W 1

The Institute of the Rubber Industry is to hold a conference on Industrial Technical Organization at the Palace Hotel, Southport, during October 9–10 Information can be obtained from the Conference Secretary, Institution of the Rubber Industry, 4 Kensington Palace Gardens, London, W 8

The Committee on Geodesy and Geophysics of the Academy of Sciences of the U S S R published in 1957 a short report of 75 pages on the recent work done in the Soviet Union in the field of seismology, seismo-geology, seismological survey, physics of the earth, tectonophysics and the age determination of minerals and rocks A list of seismological stations, abstracts of some of the papers and bibliographies of others are given

BRITISH CAST IRON RESEARCH ASSOCIATION

OPEN DAYS

THE British Cast Iron Research Association, Alvechurch, Birmingham, held two open days on May 28 and 29 The first day was arranged for visits by representatives of member firms and the second day for visitors from other research associations, Government laboratories, universities, technical colleges and local schools

The president of the Association, Mr E Player, inaugurated a new experimental cupola installation The cupola is a shaft furnace in which metal, coke and fluxes are charged alternately and air is blown through tuyères up the furnace shaft This furnace is likely to remain the most important melting unit for cast iron in Britain for very many years The reactions occurring are highly complex and the unit is capable of innumerable variations in design This experimental installation is on a full industrial scale, has mechanical charging and an extensive stockyard Use can be made of cold or hot blast, the latter being achieved by means of a separate oil-fired blast heater built with radiation and convection sections It is expected that air blast temperatures of up to 800° C will be achieved in the experimental work This range of blast temperature is far higher than that on which there is any industrial experience at present The furnace will melt up to about six tons an hour and the molten metal produced will be disposed of by means of a pig-casting machine Interchangeable well and melting zone sections have been provided so that the melting-zone profile can be changed and the furnace operated without a refractory lining in the melting zone and with water cooling The equipment is fully instrumented so that materials and thermal balances can be accurately computed.

Dr J G Pearce, formerly director of the Association, opened a new laboratory block to be devoted solely to study of fume and dust in iron foundries and its elimination This laboratory has a large experimental hall covered by a gantry crane, and is equipped for full-scale studies of the various dust extraction and ventilation problems which arise in iron foundries There is also a dust-estimation laboratory with a comprehensive range of instruments for sampling industrial dusts Estimation of the free silica content of collected dusts is carried out by X-ray diffraction Demonstrations were made of various devices developed by the Association for the control of dust produced during the manufacture of iron castings

In the chemical analytical laboratory the most important display dealt with the application of liquid/liquid solvent extraction and the removal of iron by extraction as chloride, and the acetylacetone complex was demonstrated In connexion with slag analysis, the extraction of heavy metals as diethyldithiocarbamate complexes is being applied to the determination of aluminium Another important display in this laboratory dealt with the determination of trace elements For the determination of aluminium in cast iron the element is separated as the cupferron complex after removal of interfering elements by extraction with diethyldithiocarbamate and chloroform The separation of cobalt, copper, lead and bismuth was also illustrated The determinations were completed by cathode ray polarography or spectrophotometry The demonstration of special methods of analysis was augmented by the display of a cathode-ray polarograph modified by the British Cast Iron Research Association to improve its utility and a spectrophotometer modified for single beam recording spectrophotometry in the ultra-violet region and for use as a high-sensitivity recording flame spectrophotometer

The work of the Association not only covers the material cast iron, but also the material used for the moulds into which the molten metal is cast These are usually clay-bonded silica sands, and the production of castings with good surface finish and free from defects involves consideration of their behaviour when rapidly heated by molten metal The simulation of this cannot be achieved in the laboratory by heating moulding-sand test pieces in normal laboratory furnaces since, because of the low thermal conductivity of the materials, any organic or carbonaceous materials are destroyed before the test pieces are uniformly heated These carbonaceous materials contribute in an important manner to the properties of moulding sands and are substantially not destroyed before a casting solidifies in a normal mould To overcome this difficulty a testing machine using dielectric heating has been developed which enables sand test pieces to be rapidly and uniformly heated to any desired temperature Load/deformation curves can be automatically recorded when the test piece has reached the required temperature One such unit has now been thoroughly tested and an attempt is being made to build similar equipment using a higher frequency and greater power input for still more rapid heating rates The technique should be of interest for the testing of other ceramic and refractory materials at high temperatures, particularly where rapid rates of heating are important

Cast iron is a complex alloy capable of developing a wide range of properties, depending upon the matter in which solidification proceeds The properties of grey cast iron are determined by the dispersion of the graphite phase which originates at a eutectic transformation during solidification The displays indicated that the solidification of this eutectic had received detailed study in terms of nucleation and growth It appears that elements which reduce the interfacial energy between graphite and the melt increase the number of nuclei growing at a given degree of undercooling Sulphur and hydrogen appear to reduce the rate of growth of the eutectic cells The technique by which the nucleation of the iron is estimated by means of eutectic cell counting was demonstrated and stereophotomicrographs of the graphite skeleton within each eutectic cell were shown to illustrate the growth mechanism A special cooling-curve furnace used for solidification studies was also displayed This employed a molybdenum heating element and was constructed so that there was always a constant temperature difference between the surroundings and the sample during solidification and recalescence

The application of the results of the fundamental work on nucleation to practical problems was well illustrated, particularly in connexion with the soundness of iron castings Increasing the degree of eutectic nucleation increases the tendency to shrinkage defects, and methods for reducing eutectic nucleation are being tried The laboratory findings have been well confirmed by industrial trials

Fundamental work is also proceeding on the interplay of thermal and nucleation effects in the production of chilled castings, and also on the mechanism of solidification of white cast irons in which the eutectic of austenite and iron carbide can appear in various patterns related to the nucleation of the melt and the amount of undercooling before solidification The detection of eutectic cells in white cast irons has proved difficult and the use of the reflecting polarizing microscope has so far proved to be the most useful tool

The mechanism of the corrosion attack on cast iron in diesel engine waterways has been studied and the special test rig used was demonstrated Evidence at present shows this to be caused by the accumulation of acidic oxidation products of the glycol in the coolant, the chief of which is formic acid The formation of formic acid is probably accelerated by the loss of the copper corrosion inhibitor

The problem of phosphorus in foundry pig iron was illustrated To a large extent British iron ores of low phosphorus content are exhausted. and foundry pig irons produced from home ores generally contain more than 1 per cent phosphorus This element has many harmful effects in cast iron when present in such amounts and the Association has just completed an extensive survey of the possibility of utilizing high phosphorus iron ores for the production of low phosphorus foundry pig iron It has been possible to demonstrate that by top-blowing with oxygen in a rotary Kaldo converter, the phosphorus of phosphoric pig iron can be substantially eliminated and the iron cheaply recarburized

Cast iron in steam engineering applications is generally limited to temperatures not exceeding 450° F The Association has just completed the first part of an investigation showing that this is an unrealistic limitation since almost all cast irons have dimensional stability up to at least 750° F Creep tests are in progress to provide additional evidence

Cast iron is not a truly elastic material When stressed the strain can be shown to involve a recoverable anelastic component and an irrecoverable component By a study of the stress/strain curve the latter has been shown to involve true plastic deformation and also a mechanism by which the graphite voids are increased in size The application of triaxial stress systems by means of mild notches is shown to modify the mechanical properties Typical results obtained in this investigation were demonstrated

For many years the Association has been studying the influence of the gaseous elements in cast iron, and the practical implications of this work were illustrated In particular, the influence of aluminium in cast iron in causing the decomposition of water vapour, leading to the solution of hydrogen, was emphasized with many industrial examples

The Association maintains a Foundry Operations Section to provide the iron-founding industry with an advisory service on productivity and working efficiency Recently, considerable interest has been displayed in a form of time-lapse ciné photography known as 'Memo-motion' and the equipment used and typical results obtained on foundry operations were demonstrated

The exhibition material was designed to demonstrate that the work of the Association involved largely applied research undertaken specifically in support of the iron-founding industry, its materials, processes, working conditions and productivity Many examples were given illustrating how the worker in a more or less fundamental field could receive inspiration and ideas by contact with the day-to-day problems of industry

H Morrogh

ATOMIC MECHANISMS OF FRACTURE

A CONFERENCE on "The Atomic Mechanisms of Fracture" was held at Swampscott, near Boston, Massachusetts, during April 12–14, organized by the National Academy of Sciences—National Research Council More than 400 people attended, including about twenty from overseas, and twenty-five papers were presented

Although the main emphasis was on the properties of metals, there were a number of papers dealing with non-metallic crystals, and non-crystalline solids In the last category interest centred on dynamic effects H Schardin presented some rather precise results on the measurement of crack velocities in glasses of various compositions which showed that, although it is approximately true that the maximum crack velocity is proportional to the speed of longitudinal elastic waves, there are significant discrepancies which appear to be correlated with the chemical constitution of the material H Kolsky discussed the similarities in behaviour of plastics and viscous liquids when subjected to tensile-stress pulses of short duration, caused by the stress waves from an explosion At the other extreme end of the time-scale, R J. Charles discussed the dependence upon time of the strength of silicate glasses under static loading Attributing this to the chemical action of atmospheric water vapour at the tip of a crack, he adduced supporting evidence from the behaviour of crystalline oxides under similar conditions

In the main field of interest of the conference, it was clear that the complexity of the process of fracture is now agreed Four types can usefully be distinguished (1) ductile, (2) brittle, (3) creep, (4) fatigue It should, however, be emphasized that this is no more than a classification of convenience, each heading probably covers a variety of processes, and when any particular body changes from one piece into two pieces a selection of these processes may have been involved, according to the conditions of the experiment An extreme case arises when a crystal of a soft metal draws down, in tension, to a chisel edge or a point The mechanism, doubtfully included under the general heading of fracture, is the flowing of material away from the developing neck, by single or multiple glide processes It was suggested that the central, fibrous part of the typical cup-and-cone tensile fracture of, say, a copper bar might be essentially similar to this A paper by C Crussard *et al* emphasized the value of the electron microscope in the study of such fracture surfaces—a value which arises not so much from its high resolving power as from its great depth of focus Crussard showed that in such a fibrous ductile fracture there is evidence of repeated nucleation of new cracks ahead of the growing tip of the major crack, such nucleation taking place usually at minute inclusions in the metal The new cracks may then join with the major crack by a process of repeated necking down, as just suggested

R W K Honeycombe and C J Beevers showed that, by suitable choice of conditions, such necking can be suppressed, even in single crystals of a face-centred cubic material, and that when this is done one obtains a mode of separation which can be more properly called a true ductile fracture, the separation of the two parts taking place along a previously heavily deformed glide plane and being apparently controlled by the resolved shear stress on this plane On the other hand, single crystals of iron, tested at low temperatures by N P Allen and B Edmondson, either neck down to 100 per cent reduction of area, as already described, or else cleave along the {100} cleavage plane without obvious prior slip The choice between the two modes of behaviour is determined by the direction of the tensile stress relative to the crystal axes, and the transition is quite sharp

The topic which received the greatest amount of attention during the conference was the well-known ductile – brittle transition in polycrystalline iron which normally takes place rather below room temperature A paper by G T Hahn, B L Averbach, M Cohen and W S Owen reported an extensive series of observations on the tensile fracture of mild steels, of various compositions and grain sizes, over the temperature range 20–290° K , which showed that the phenomena are more complex than had perhaps previously been realized In particular, the authors claim that different processes are important in different ranges of temperature—other things being equal—and that mechanical twinning plays a decisive part at the lowest temperatures

Microscopic observations of specimens broken, or almost broken, under conditions near those obtaining at the brittle – ductile transition showed the existence of numerous micro-cracks, each usually confined to a single grain The frequency of occurrence of such cracks varied systematically with the conditions of the test and the authors maintain that it is necessary to subdivide the process of fracture in this transition range into (*a*) true initiation in which some plastic deformation is probably essential, (*b*) growth within the original grain, (*c*) propagation through the rest of the specimen A useful concept which arises is that the 'effective' value of the surface energy of the newly formed surfaces may be much larger—the authors deduce 10 times larger—for (*c*) than for (*b*) This is indeed reasonable in the light of some of the fractographic studies of J R Low, which show very clearly the change of character of a cleavage surface which can take place when the crack passes from one grain into another less favourably oriented for cleavage

A contribution from N J Petch summarized his own extensive work, relevant to the more metallurgical aspects of the same problem In addition to the grain size, temperature, and strain-rate, which are commonly recognized as important variables, he discussed also the mechanisms by which the carbon, nitrogen and other elements commonly present in steels affect the various stages of the fracture process, and the ways in which their influence can be modified by previous mechanical and thermal treatment The introductory paper by A H Cottrell also dealt with the brittle – ductile transition at some length, in addition to giving a general survey of the whole subject of the conference Although some points of controversy remain, and although much detailed work remains to be done, it appears that the broad outlines of the explanation of the ductile – brittle transition are becoming settled

The two main contributions on creep fracture, namely, on slow fracture at temperatures which are high relative to the melting point, came from N J Grant and R C Gifkins The features which distinguish this type of failure from the others are the considerable importance of grain-boundary sliding and grain-boundary migration, the comparative ease of dislocation climb processes, and the possibility of deformation by the migration of point defects under the action of stress It was made very clear that these four processes can be inter-related in several ways, and that they can all be inter-related to any deformation by dislocation glide which may be taking place in the body of the grains Failure is often, but not always, intergranular, and is often, but not always, associated with the presence of 'voids' in the grain boundaries The fracture behaviour was reported to be particularly sensitive to the presence of small amounts of impurity in a nominally pure metal The paper by Gifkins summarized some of the earlier experimental work, which is considerable in quantity and not always self-consistent It is clear that it is likely to be some time before the present confusion approaches anything approximating to a unified body of knowledge, although the general lines of the pattern are beginning to emerge

The problem of fracture during fatigue is perhaps in the least satisfactory state of all Of the papers presented at the conference, most were concerned with the early stages of the process W A Wood described the interesting results obtained by a taper sectioning method applied to a partially fatigued copper specimen As with so many other papers on other topics, the impression given by this work is that the mechanism of fracture is more complex than had hitherto been supposed The emphasis is on the events taking place close to the surface of the solid, and leading up to the formation of a true crack E S Machlin and A J McEvily described experiments on four inorganic crystals which seem to show an inter-relation between liability to fatigue fracture and the ability of the crystal to become deformed by cross-slip , the possibility of the formation of 'extrusions' from the metal surface also seems to be correlated with both these features A similar point emerges from a comparison of two papers on copper by W A Backofen and N Thompson, respectively, one of which dealt with the effect of crystal orientation on liability to fracture while the other related crystal orientation to extrusions

Mention must also be made of the contribution by E R Parker on the cleavage fracture in tension of single crystals of magnesium oxide These observations, and similar work by Stokes *et al* , mentioned in the course of discussion, demonstrate the advantages to be gained by experimenting on ionic rather than metallic crystals, and emphasize a point that was made on a number of occasions This is that, on close examination, no crystal breaks in a truly brittle manner , the fracture is always preceded by some small amount of plastic deformation This is one of the key points in connecting theories of fracture with current views on the mechanical behaviour of crystalline solids The other general feature of the proceedings, already mentioned, was the evident fact that in no circumstances is fracture a simple process The realization that "when a problem is difficult, it is probably two problems" is perhaps the most important step on the road to a solution

N Thompson

OXIDATION OF ORGANIC COMPOUNDS

A SYMPOSIUM on the oxidation of organic compounds was held in the Stern Hall at Queen Mary College, University of London, during April 13–14

In his opening address Mr D A C Dewdney, director of Esso Petroleum Co , Ltd , spoke of the importance of a free exchange of scientific information and the need of still further fundamental research into basic problems , an improving standard of living and higher productivity are largely dependent on the commercial application of original scientific discoveries In welcoming visitors to the symposium, he referred especially to those from the U S S R and Czechoslovakia

The first part of the scientific discussion was concerned with the course of the oxidation of saturated hydrocarbons by chromic acid in acetic acid containing some sulphuric acid From the papers and the discussion which developed there was general agreement that the first recognizable stage in the oxidation is hydrogen abstraction from the hydrocarbon, and that the factors which influence the speed of the reaction are mainly steric and configurational The same factors also determine the rate of oxidation by chromium trioxide in anhydrous media

Dr J Roček (Institute of Chemistry, Czechoslovak Academy of Science, Prague) reported that *n*-paraffins are oxidized at a rate directly proportional to the number of methylene groups, the rate constant for any individual member being $k_n = k_{CH_2}(n - 2)$, where n is the number of carbon atoms and k_{CH_2} the rate constant for the oxidation of a single methylene group The relative rates of oxidation of the methyl, methylene, and methine groups in open chain hydrocarbons have been found to be 0 015 · 1 · 32–77 Measurements of the rate of oxidation of *cyclo*alkanes disclosed some interesting anomalies

The oxidation-rate of the tertiary CH-group is found to vary somewhat with the bulk and structure of the neighbouring alkyl groups , these variations are due mainly to polar factors and are similar to changes in rates of solvolysis of the corresponding tertiary chlorides Only in special cases has steric retardation been found , steric acceleration does not play any detectable part in the acyclic series It is concluded that the rate-determining step is the formation of a carbonium ion by way of a hydride ion transfer from the hydrocarbon molecule to an oxygen atom of the oxidizing agent

Prof K B Wiberg (University of Washington) from a study of the rate of oxidation of diphenylmethane and of its nuclear substituted derivatives in 95 per cent acetic acid concluded that the oxidation proceeds by initial removal of a hydrogen atom to give a benzhydryl radical which is then oxidized directly to benzophenone In support of such a mechanism, oxidation of optically active 3-methylhexane gives an optically active tertiary alcohol, a result which seems to exclude the initial formation of a carbonium ion The formation of camphenilanic acid by the oxidation of *iso*camphane is also cited in support of that view. Further evidence of an indirect nature is derived from a study of the action of chromyl chloride on propylbenzene-$\beta\beta d_2$, benzyl methyl ketone is among the products, and it was found to have one deuterium atom in the α-position, indicating a deuterium shift during the reaction

The oxidation of tertiary paraffins by chromic acid in presence of sulphuric acid is known to lead to tertiary alcohols, and the course of the reaction can be interpreted in terms of dehydration of the alcohol to olefin In a study of the oxidation by Dr W J Hickinbottom (Queen Mary College, London) the conditions were selected so that tertiary alcohols could not be formed, by using chromium trioxide in acetic anhydride Under these conditions, paraffins gave products which were qualitatively identical with those from the corresponding olefins in presence of weak acids Further, some of the paraffins gave unsaturated products From these results and from quantitative measurements of the rates of oxidation it was concluded that tertiary paraffins are attacked preferentially at the tertiary carbon atom with the subsequent formation of an olefin

A possible key to the oxidation of paraffins by chromic acid may lie in the behaviour of the alcohols which may be derived from them by oxidation Our knowledge of the course of the oxidation of alcohols is based on the work of Prof F H Westheimer (Harvard University) In continuation of this work, he described, with Y E Chang, a study of the oxidation of pinacol and its monomethyl ether. A feature of the pinacol oxidation is that it proceeds 2 7 times as fast in deuterium oxide as in water This was interpreted to mean that the hydroxyl bond is not cleaved in the rate-controlling step of the oxidation The relative merits of an ester mechanism and hydride abstraction were discussed and many useful ideas exchanged

Dr W A Waters (Oxford) reviewed the relationship between vanadate and permanganate oxidations The role of trivalent manganese and of organic free-radical intermediates in permanganate oxidations was reviewed Features diagnostic of one-electron oxidations were brought to notice It was stressed that lack of diagnostic evidence need afford no grounds for the rejection of a reaction mechanism

Dr J W Ladbury (I C I , Ltd , Plastics Division, Welwyn Garden City) and Dr C F Cullis (Imperial College of Science and Technology, London) discussed the oxidation of inorganic and organic compounds by permanganate The development of reaction-rate with time depends on the nature of the compound undergoing oxidation The observed types of behaviour fall, broadly speaking, into four categories according to the shape of the reaction – time curves Thus there may be (1) a continuous decrease in rate with time, usually not strictly according to a second-order kinetic law; (2) an initial autocatalytic development of reaction-rate followed eventually by a decrease due to consumption of reactants; (3) an initial high rate of reaction which rapidly decreases almost to zero and is then followed by an autocatalytic reaction of type (2); (4) an initial high rate followed by a linear reaction – time curve. These various kinds of behaviour were discussed and reasons proposed for the characteristic differences observed according to the nature of the substrates. In the discussion on this, Prof. N. M. Emanuel (Moscow) directed attention to the resemblance between type (3) and the oxidation behaviour he had observed using oxygen.

Dr. S. Littler and Dr. W. A. Waters (Oxford) reported that pentavalent vanadium becomes an oxidizer in acid solution, the active agents being cations, for example, VO_2^+, $V(OH)_3^{2+}$, depending on the acidity, which reduce only to the oxidation-level of quadrivalent vanadium with organic compounds. Kinetic studies were reported of some glycol fissions and of the oxidation of *cyclo*hexanol. In the latter case an initial rapid esterification seems to be involved though the rate-determining stage involves C—H bond fission. Isotope effects in *cyclo*hexanol depending on the oxidizing ion were discussed and a cyclic mechanism proposed.

The oxidation of saturated hydrocarbons in the liquid phase by air is now a matter of both industrial and theoretical importance. Prof. A. N. Bashkirov (Moscow) described his work on the oxidation of the higher paraffins. In this he described a very important development, namely, that the oxidation can be arrested at a predetermined stage. By using boric acid and selecting suitable conditions—a temperature of 165–170° C. and a nitrogen–oxygen mixture containing 3–4·5 per cent of oxygen—the higher paraffins can be converted into the corresponding alcohols in 70 per cent yield. There is practically no degradation of the hydrocarbon molecule and all the possible secondary alcohols are formed.

Prof. N. M. Emanuel (Moscow) discussed a number of interesting aspects of slow branched-chain oxidation reactions of hydrocarbons, and reference was particularly made to the capacity for auto-acceleration and self-propagation and the control of these reactions by homogeneous catalysts. Some of the ideas developed in this paper were shown to have application in biological processes such as retardation and suppression of the growth of malignant tumours in animals.

Prof. H. B. Henbest (Queen's University, Belfast) reported that trialkylamines are readily oxidized by a large variety of reagents, the initial products being usually N-oxides, enamines, or carbinolamines. Depending on its structure and the reaction conditions, a compound of the last type may be oxidized further to an amide or may cleave to a mixture of a secondary amine and a carbonyl compound. Analogous compounds may be formed in the oxidation of dialkyl anilines, but in this series additional products are possible if nuclear positions become involved in the reaction.

A general survey of the field was presented, followed by a more detailed discussion of some of the reactions of trialkylamines and dialkylanilines with N-bromosuccinimide, ceric salts, *p*-quinones, di-tert-butyl peroxide, and benzoyl peroxide. The results with dialkylanilines suggest that the three primary oxidation processes of electron removal, hydrogen atom removal, and hydride ion removal, can all occur, the choice for any particular amine being mainly dependent on the type of oxidizing agent used.

Some known features of oxidations by persulphates were summarized by Dr. R. G. R. Bacon (Queen's University, Belfast) and new data presented. Persulphates may be employed (*a*) as aqueous solutions, undergoing thermal or photo-induced decomposition; (*b*) in strongly acidic solutions; (*c*) in alkaline solutions; (*d*) in redox systems, where persulphate acts in conjunction with, for example, an oxidizable metal ion. The use of persulphate in redox systems was discussed with emphasis on the value of silver ion as the redox partner. Applications of this method to oxidations of alkylbenzenes, phenols, alcohols, carboxylic acids, and amines, were described.

In summing up the proceedings of the symposium, it can be said that its success as a scientific meeting depended very largely on the free and uninhibited exchange of ideas and the discussion of current and unpublished work now in progress.

W. J. Hickinbottom
R. F. Garwood

GAS CHROMATOGRAPHY

The Gas Chromatography Discussion Group associated with the Hydrocarbon Research Group of the Institute of Petroleum has now completed its reorganization following an inaugural general meeting last autumn, held at University College, London, on September 23, 1958, and the first annual general meeting at the Imperial College of Science and Technology, London, on April 10, 1959. Both meetings were held in conjunction with an informal symposium and were attended by more than two hundred participants.

The success of the new organization may be judged from the total enrolled membership, which is now about 220, of which some fifty are from the Continent or the United States. The Group has now organized four one-day informal symposia in Britain and the second formal symposium in Amsterdam in the spring of 1958, which was attended by nearly five hundred participants from twenty-one different countries. In addition, it has published two papers and arranged for the manufacture and sale in the United Kingdom of specially prepared stationary phases and supports in an endeavour to standardize experimental procedures for determining, and methods of presenting, gas chromatographic data. Arrangements are being completed for the collection and distribution of the latter to members, together with abstracts of papers on the technique from more than sixty journals. The future programme tentatively includes another informal symposium to be held at Bristol in the autumn of 1959, and the third formal symposium in Edinburgh during 1960. The outstanding contributions of Dr. A. J. P. Martin, both in originating gas–liquid chromatography and in many important later developments, have been recognized by the Group by bestowing on him honorary life membership.

The technical part of the meeting at University College, London, on September 23, 1958, was introduced by Prof E D Hughes, who gave a short welcoming address commenting on the rapid growth of the Group Dr D Ambrose, the local organizer, then presented proposals on behalf of the Group for the determination of retention volumes under standard conditions Various practical points about the experimental procedures were discussed, including temperature control and the life of columns

Dr G A P Tuey described the work done in his laboratories in preparation for the sale of standardized materials for use as stationary phases Extensive tests had been made of volatility in an apparatus which simulates conditions in the chromatographic column but allows a gravimetric determination of the loss at a particular temperature The rate of loss with time was determined and a final specification includes a figure for initial loss, the steady rate of loss and relative and specific retention data

The comparison of detectors for gas chromatography was the subject of a paper presented by Dr I G McWilliam Detectors were discussed in terms of sensitivity, response time, relationship of detector output to molecular parameters and ease of construction and operation The sensitivity is best stated in terms of gas concentration, and the unit gm /ml of carrier gas was advocated. Base-line noise (μV) and drift (μV /hr) should also be stated The response time must be small enough for negligible distortion of the true peak shape to occur If the relationship between detector output and some molecular parameter is known, quantitative analysis without calibration is facilitated Although all these factors must be considered in selecting a detector, the final choice frequently depends upon the ease of construction and operation Of those in use, Dr McWilliam considers the single-jet flame ionization detector the simplest

Dr K R Garrett presented a report on a programme of co-operative analysis of hydrocarbon gases organized by the Institute of Petroleum Cylinders containing sales butane and a cracked C_4-mixture have been circulated among participating laboratories, where they have been analysed using a range of techniques Preliminary results indicate the importance of standardization of methods of taking samples from the cylinders and enable some assessment to be made of the reproducibility of possible standard procedures

An interesting study of alumina as a packing was described by Mr C G Scott Several methods of achieving different levels of adsorption activity had been tried, but the most promising seemed to be the addition of small quantities of water and silicone oil With optimum proportions it was possible to maintain the ability of the adsorbent to separate hydrogen and methane but with much reduced retention volumes for the higher hydrocarbons An analysis of a gas mixture containing hydrogen, C_1-, C_2-, C_3-, C_4- and C_5-hydrocarbons was therefore possible in a single run at constant temperature

Prof R M Barrer welcomed the Group to the Imperial College of Science and Technology, London, on April 10, 1959, congratulating it on the excellence of the meetings it organized and the vigour and enterprise shown by such a comparatively new organization The local organization of this meeting was carried out by Dr G J Minkoff The first paper, presented by Dr A Goldup, was concerned with the potentialities of the new coated capillary columns in the petroleum industry He described a compact practical apparatus with which capillary columns had been operated at temperatures up to 250° C Column efficiencies in excess of 100,000 theoretical plates had been obtained with metal tubes ten-thousandths of an inch in diameter and 250 ft long coated with squalane or 'Apiezon' grease A novel sample introduction device was described in which the very small samples required for the column were obtained by a dynamic division of the carrier gas at the column head The use of these high-efficiency columns in the analysis of various petroleum products and in geochemical prospecting was illustrated Mr B H F Whyman, another of the authors of this paper, in a prepared contribution to the discussion, described a simple apparatus for drawing long lengths of coiled glass capillary, which show certain advantages over metal capillary

Mr R P W Scott then described the use of fine nylon tubes (0 01 in , 0 02 in and 0 1 in in diameter) as capillary columns Simple coating procedures were used, the transparency of the nylon being helpful in adjusting the rate of flow of the solution of the stationary phase through the tube A column 1,000 ft in length of 0 02 in diameter coated with dinonyl phthalate gave a maximum of 750,000 plates, but the efficiency tended to fall off rapidly with increasing retention time to about 250,000 plates Operating temperatures were limited to about 100° C with present tubing, but 180° C seemed feasible with other polymers A very active discussion took place following these two papers and it is obvious that there is much interest in these new capillary columns, which M J E Golay described for the first time in the autumn of 1957

A new detector employing changes of dielectric constant developed primarily for preparative-scale gas chromatography was described by Mr D W Turner For this application, where high sensitivity is not so important as for analytical work, the detector has the advantages of being largely independent of flow-rate, non-destructive and reasonably robust It employs a novel circuit which is very sensitive to the minute capacity changes produced in the detector cell, and with slight modifications is easily used with solutions such as are encountered in liquid chromatography

Mr V Willis presented a paper on the application of gas chromatography to process stream monitoring, where an instrument is required automatically to sample and analyse a gas or liquid stream over long periods A column-life of two years is aimed at, but is difficult to attain with many stationary phases Although a useful survey of requirements was given, unfortunately few constructional details were available

Finally, in the last paper Dr S H Langer discussed his work on improvement in stationary phase selectivity He exemplified this with his results using tetrahalophthalate esters for the separation of the aromatic hydrocarbons These esters had been selected in an endeavour to exploit the complex formation known to exist between tetrachlorphthalic anhydride and condensed aromatic hydrocarbons Effective separations of the lower aromatic hydrocarbons had been obtained and separation factors and activity coefficients were compared with other stationary phases It seems likely that the electron-deficient tetrahalo-substituted ring interacts with the aromatic compounds by a charge-transfer mechanism

RADIATION SAFETY AND HEALTH PHYSICS

By J W. LUCAS

THE Windscale reactor incident of October 1957 involving the release of radioactive fission products into the atmosphere[1], undoubtedly served to focus the attention of the general public on to the hazards of ionizing radiation and to the increasing risks of exposure Interest has also been aroused by the publication of reports by the Ministry of Health, Medical Research Council[2] and the U N Scientific Committee[3] The rapid expansion of the nuclear power programme, coupled with the increasing employment of sources of ionizing radiation in industry, medicine and research institutions, and also nuclear weapon testing, demands an increasing vigilance and knowledge of the risks and safety precautions on the part of many people The U K Atomic Energy Authority has an excellent record of safety both with respect to its own staff and to the general public in the vicinity of its establishments, and has also exercised a rigorous control over the discharge of waste radioactive products into the environment[4] The Fleck Committee set up to inquire into the organization for control of health and safety[5] nevertheless recognized the need for a rapid expansion of health physics and safety staffs in the Authority, and recommended that the Research Establishment at Harwell should set up a national training centre for health physics and nuclear safety staff to cater for persons both inside and outside the Authority

A number of short courses on "Radiological Protection" have already been held at the Isotope School, Harwell, but it was felt that there was scope for a college of technology to undertake similar work An approach was therefore made to the United Kingdom Atomic Energy Authority, Industrial Group, at Risley, in the spring of 1958 with the view of introducing courses in the Liverpool College of Technology later in the year A scheme was prepared in conjunction with the Authority and this article provides a brief interim report, based on experience of three courses which have been run in late 1958 and early 1959

Each course is of a fortnight's duration The available places on the three courses have been taken up by representatives of the U K Atomic Energy Authority, public health departments, factory inspectorate, local industry, insurance, and education, members attending include medical officers, physicists, engineers, insurance accident surveyors, chemists, public health inspectors and safety officers

The aim of the courses has been to provide an introduction to, and a general survey of, the problems of radiological protection against all forms of ionizing radiation The very specialized problems of reactor safety and the processing of nuclear fuel elements have not been dealt with specifically, except in so far as environmental effects may be involved Special attention in both lectures and practical work is, however, given to subjects such as the comparative properties of radiations, the sources of radiation including background and fall-out, the effects of radiation on plants, animals and man, contamination and decontamination, waste disposal, health physics instrumentation and monitoring procedures, absorption of radiation and shielding. Table 1 summarizes the lecture and practical topics which have been covered on the early courses, the programme is rounded off by visits to local institutions and works, by the exhibition of films, and by discussions

The programme of practical work has been devised to provide a series of short-term experiments, underlining the basic problems of a comprehensive protection service Some aspects of the practical work and the results which have been obtained have already proved of considerable interest and are briefly described It is hoped to publish the detailed observations at a later date

The experiments in radiobiology have been singularly successful in demonstrating the fate of various radioisotopes when brought into contact with biological organisms to be found in a natural environment The techniques have been previously described by D C Pickering and myself[6] The experiments with blanket weed (*Microspora*) have demonstrated conclusively the ability of the algae to concentrate many isotopes from their environment, and have particularly served to emphasize the importance of properly planned disposal procedures A safe procedure for radioactive liquid waste is afterwards demonstrated to members of the course

Table 1 SYLLABUS OF LECTURES AND PRACTICAL WORK

Lectures			Practical	
Section	Topics	No of hours	Subject	No of hours
Radiation and its sources	Comparative properties, units and calculations of dosages, background and fall-out, nuclear reactors, particle accelerators	6	X-ray equipment and sealed sources Techniques with open isotopes—counting and identification	1 7
Measurement and detection of radiation	Principles of measurement, types of counter and H P instruments	5	Calibration and operation of H P instruments Dosage calculations	3
Interaction of radiation and matter	Radiation chemistry, radio-biology-genetics, metabolic processes	6	Radiobiology	7
Radiological protection	M P L's and M P C's, control of internal and external radiation in laboratories and plants, medical care, waste disposal, legal requirements, industrial practice, X-ray units	10	Contamination—prevention and removal Waste disposal Shielding Radiation monitoring Air sampling	4 1 2 2 2

Lectures have been presented by members of the Health and Safety Branch of the U K Atomic Energy Authority Industrial Group, Factory Inspectorate and the Universities of Leeds and Liverpool, in addition to College staff

The importance of thorough testing of materials of construction for contamination properties is not generally appreciated A fairly extensive investigation was undertaken by P C Thompkins *et al* in the United States[7], but data concerning materials available in Great Britain are not readily available A simple test procedure has been devised to provide a measure of contamination for a range of materials and isotopes The method also enables a variety of surface protecting agents and decontamination procedures to be investigated Results on a wide range of materials are gradually being accumulated to provide some form of quantitative assessment of comparative degrees of contamination

The first three courses have provided invaluable experience and have suggested numerous lines of future developments In particular, more advanced courses of three to six months duration are under active consideration in addition to an expansion of work on a number of research projects, leading to the new M C T award

I wish to acknowledge my indebtedness to the U K Atomic Energy Authority for advice in the preliminary stages and assistance with lectures and equipment, to Prof F W Spiers for advice and lectures in the early stages, to Prof A B Semple (Medical Office of Health, Liverpool) for advice and lectures, to Dr Sing for his constant and active support and encouragement, and to Mr D C Pickering for his indefatigable contributions in radiobiology

BRITISH UNIVERSITIES FILM COUNCIL

THE twelfth annual general meeting of the British Universities Film Council took place in Cardiff during May 8–10 This short survey describes its development and traces the main tasks which it set itself in the field of university teaching and research This year's discussions and lecture-demonstration programmes included a report on closed-circuit television relay experiments for 'overflow' lecture rooms, a survey of television university courses in the United States, and a demonstration of visual-aid equipment for the ideal lecture room Among other things, the Council is at present interested in liaison with the International Scientific Film Association, further exploration of a possible lectureship in film and continuance and improvement of the catalogue and journal

The present honorary secretary of the British Universities Film Council, Mr C J Duncan, of King's College, Newcastle, recently reviewed the short history of the Council in an address at Gottingen He rightly emphasized that the Council is a gathering of university representatives, brought together through a common interest in films for university purposes This at once makes clear the practical advantages of personal contacts developed between individuals in each university or college, and of the direct personal ways in which they can in turn infect their colleagues with their own enthusiasm for using or making films

However hampered by financial stringency—in a medium far less expensive than is commonly assumed—however different the rate of progress in member institutions, that keynote of enthusiastic co-operation has been a feature of the Council since its foundation in the autumn of 1948 A few months earlier, the Cambridge University Film Council had been set up and it was this body which called the first gathering of 'film representatives' from all universities and colleges The aims of the Council, as then laid down, have not materially changed since then, although the emphasis may have varied Briefly stated, these aims are the promotion of the production, distribution and use of films in university teaching and research The aims have been practically pursued in hard-working sub-committees which act as special reporting and planning bodies to the executive and the Council, which meets annually each year at a different university The tonic effect of the visits has already been noticed, for during the meeting, the host-university staff and students, and interested bodies from outside, are invited to attend demonstrations, exhibitions of equipment, and programmes of films of interest to universities Past chairmen have come from Cambridge, Edinburgh, the Imperial College of Science and Technology, London, and the Royal Technical College, Glasgow

The Council's membership has grown to include to-day, as full members, thirty-two institutions in Great Britain alone, with a good hope of soon enlisting in addition the new colleges of advanced technology (Loughborough is already a member of long standing) Among the Council's associate members are the Scientific Films Association, London , Shell Public Relations Department , the French Institute, London , and Eastman Kodak Co (Non-Theatrical Film Section), Rochester, New York Close contacts and visiting arrangements exist with Dutch, German, French and Polish organizations mainly devoted to research films This contact with foreign bodies is expanding and is promoted by members attending international gatherings, such as the annual congress of the International Scientific Films Association

Nearly all British universities and colleges have through their delegates participated in the work of the executive or its sub-committees With the help of the British Film Institute and the support of subscriptions from member universities, the Council collects and disseminates information and advises on suitable films, or relevant parts of films and related material Good liaison exists with organizations doing comparable work in education, research, industry and commerce The Council's library, centrally housed at the British Film Institute, contains films recommended by the Library Sub-Committee, but only a fraction of what would be desirable is in fact there The Catalogue, in the hands of an active and energetic sub-committee, conducted from Glasgow, already contains more than 1,500 titles , a card index is issued free to members and can be bought by others It consists mainly of films on pure and applied science, but no subject is ignored which is within the scope of a university Medical films are also listed, but the Committee tries to avoid duplication of the work of the Film Committee of the British Medical Association and related organizations Catalogues are, as a rule, easily accessible in university reference libraries, and many member institutions have as many as three copies in constant use Index cards are 2*d* each to non-members (minimum 5*s*), and a revised list was published early in 1957 The Council also publishes the *University Film Journal* about three times a year, which contains relevant articles of interest to staff and students in universities, important reprints and as much news material from home and overseas as possible At the time of writing, inquiries are being circulated throughout all member universities on the quality and kind of film needed by lecturers and professors, and what special film equipment is being held and would be available to colleagues

The Council has successfully sponsored special conferences on the use of films in such diverse fields as modern languages (at the Institut français), arts subjects (at the Institute of Education, London), chemical engineering (at Birmingham), psychology (at University College, London) , it has also, in the past, assisted in the selection of films for the annual British Association meetings J Horne

UNIVERSITIES AND ADULT EDUCATION IN BRITAIN

THE total number of courses conducted in Britain by university extra-mural departments during 1957–58 were rather fewer than during 1956–57, but still above the figure for 1955–56 Although this may give cause for modest satisfaction, the slight decline which took place was not evenly spread over the whole of the work but affected with disproportionate severity tutorial classes and residential courses, two branches of work which universities have traditionally cherished* Since the beginning of the current decade the tendency has been for the number of tutorial classes to decline, but the sharp drop during 1957–58 is without recent precedent

There are signs that the policy of financial limitation initiated a few years ago is now affecting extramural work, particularly in the type of course provided In such work it is difficult to stand still , an attempt to curb developments inherent in the work is apt to lead to retrogression Many extra-mural departments were just able to hold their own, or reported small increases in the number of classes (usually shorter classes) in spite of grant problems

At Glasgow it was reported that "during the past year some of the emergency cuts which had to be made, such as the reduction of the library grant, are likely to have a harmful effect on the quality of the work unless they can soon be restored" Nottingham had to reject ten requests from classes because of shortage of funds At Oxford also there were financial problems "The University Chest found itself forced to cut its grant for extra-mural work, with the result that the adult scholarship scheme was suspended and the number of classes fell more sharply than at any other university " The Delegacy for Extra-Mural Studies restated, in a memorandum submitted to the Hebdomadal Council, its firm belief in the value and importance of extra-mural studies, and "its regret that the work must be contracted at a time when the need for it had become even more urgent"

THE CENTRAL AGRICULTURAL RESEARCH STATION, CARAPICHAIMA, TRINIDAD

By Dr A J. VLITOS
Director

THE new Central Agricultural Research Station located at Carapichaima, Trinidad, is an institution intended to foster fundamental and applied research relative to sugar cane Supported by private funds (Caroni, Ltd , and Ste Madeleine Sugar Co , Ltd) the new Research Station is concerned with the agronomy, physiology, pathology, entomology, and biochemistry of sugar cane with the ultimate aim of applying in the field new information which may be forthcoming from the basic investigations

The main section of the Station houses the physiology, pathology, entomology, and biochemistry units in an air-conditioned laboratory, fully equipped with the facilities required to carry out the research programmes Adjacent to main laboratories are dark rooms and a temperature-controlled light room suitable for the growth of plants under controlled environmental conditions A library, containing the pertinent scientific journals, is located in the east wing of the main building

An agronomic programme, more applied in nature, will complement the fundamental studies in physiology A major effort is being directed towards the control of froghopper (*Aeneolamia varia saccharina*) and the other major insect pests of cane in Trinidad Chemical weed control, as well as new methods of cultivation, are also under investigation Physiological and biochemical studies are concerned with the auxin relations in the developing cane seedling, from seed to flowering In addition to the auxin studies, several investigations on mineral nutrition and photosynthetic efficiency will round out the physiology programme The pathology programme is devoted to a thorough study of the rhizosphere of sugar cane, including a taxonomic investigation of the microflora and microfauna residing in the immediate vicinity of the root system, as well as an analysis of the interrelationships between the secretions of the root system and the microbial population

THE LISTER INSTITUTE

THE report of the Governing Body on the work of the Lister Institute for 1959 describes a wide range of investigations* In the field of microbiology the Guinness–Lister Unit continues its exploration of the genetics of *Salmonella* bacilli, mainly in terms of the biochemistry and genic control of the synthesis and function of flagella, using the bacteriophages that infect these bacilli to transduce genetic material from one kind of bacillus to another The bacteriophage transduction technique has been extended to staphylococci The other purely biological study concerns the cytology of certain free-living, flagellated protozoa

Studies by Institute staff into the immunology and pathology of infective diseases are concerned with infections by viruses, pleuropneumonia-like organisms, bacteria and protozoa

The isolation of the viruses of trachoma and of inclusion blennorrhœa has opened up a large field of study, both in Gambian laboratories of the Medical Research Council's Trachoma Unit, where the epidemiology of trachoma is being studied, and in the Council's Unit in the Department of Virology The ready infection of the baboon's conjunctiva with the virus of inclusion blennorrhœa provides an experimental model in which to study the practicability of prophylactic immunization in the related infection by trachoma virus In the Smallpox Vaccine Department, there is continued progress towards making vaccine from vaccinia virus grown in tissue culture, as an alternative to virus harvested from the skin of infected sheep

The investigation of a bacterial urethritis in man established a genital type of pleuropneumonia-like organism as a possible cause In man, however, the incidence of antibodies to pleuropneumonia-like organisms was not correlated with the presence of the organisms in the genitalia, so a detailed study of the relation of the pleuropneumonia-like organism antibody response to infections by the organism is being made, in the first place in experimental infections of the rat

The immunological study of bacterial infections shows further progress in identifying the two antigens of the whooping cough bacillus responsible for prophylactic immunization and the exclusion of the histamine-sensitizing antigen as being immunogenic as well as a search for immunizing somatic antigens in the diphtheria bacillus and an analysis of the iota toxin of *Clostridium welchii*, a bacillus that may play an ætiological part in infective hæmorrhagic fever The study continues of the biologically active substances formed when diphtheria anti-toxins are refined by proteolysis, and of the actual enzymic process of refinement

With pathogenic protozoa, the antigenic analysis of *Trichomonas* species continues and a new field has been entered in an attack on the immunology of trypanosomiasis Soluble trypanosome antigens, formed during experimental trypanosomiasis of the rat, are under investigation and the *in vitro* culture of trypanosomes is being attempted to provide bulk material for antigenic analysis of these protozoa

The refined serological methods devised to identify the animal source of food for blood-sucking insects continues to provide valuable facts about the feeding habits of tsetse flies and mosquitoes in regions where these insects are vectors, or possible vectors, of disease

Work on the relation of early tissue reactions to defence against microbial infection continues The tissue response to various kinds of injury, including infection, was explored to determine the role, if any, of the serum proteases which increase capillary permeability The investigation of early non-specific resistance to bacteria was extended to infections by tubercle bacilli

The biochemical researches mainly concern three kinds of substances—the blood group substances, the cellular phospholipids and starches

During the year the problem of homogeneity of the blood-group specific substances isolated from secretions and digests of tissue has received careful attention and new methods of analysis have revealed that in the natural secretions blood specificity is associated with at least two types of mucopolysaccharide molecule Progress was made in the separation and purification of enzymes which destroy the serological activity of the blood-group substances, and the chemical changes associated with loss of activity were investigated

The phospholipid study is at present directed to defining the constitution of tissue phospholipids which, although ill-described, are known to be metabolically active The structure of one of these, cardiolipin, has been elucidated and work is proceeding on the fatty constituents of the plasmalogens and the polyglycerophosphates

The plant enzymes established as responsible for the synthesis and degradation of starch have been characterized in terms of their individual actions on starch These enzymes were studied particularly in respect of their combined actions in systems thought likely to reproduce the conditions in which starch is synthesized *in vivo*, and of their separate actions on chemically modified substrates, designed to yield information on the specificity of the enzymes

On human plasma proteins, the Institute's work is concerned with the isolation, refinement, characterization, assay and in some cases clinical trial of the various biologically active proteins of human plasma

The difficulties of specifying the potency of preparations of anti-hæmophilic globulins for use in hæmophiliacs has necessitated a re-examination of modes of assay; clinical studies of the efficacy of the human preparation are in progress The therapeutic value of γ-globulin in the treatment of hypogamma-globulinæmia is the subject of another clinical study Studies of the isolation of active proteins include that of plasmin for clinical use and the conditions of its activation from the precursor plasminogen during the fractionation of serum as well as that of oxidase cæruloplasmin Pathological studies include investigations of the so-called 'macroglobulins' that occur in hyperglobulinæmic sera and of the proteins that appear in the urine of man and animals poisoned by heavy metals

A THEORY OF THE ABRASION OF SOLIDS SUCH AS METALS

By J. GODDARD, H. J. HARKER and H. WILMAN

Applied Physical Chemistry of Surfaces Laboratory, Chemical Engineering Department,
Imperial College of Science and Technology, London, S.W.7

ABRASIVE wear is particularly important in machine bearings and gears[1] as well as in the mechanical surfacing of metals. Nevertheless, hitherto there has been no adequate theory to account quantitatively for the observed friction and wear of metals during abrasion. In particular, no simple relation between wear and friction has been observed. We have now observed such a clear and interpretable relation (see equation 1, below), and this has led us to develop the theory outlined below, which accounts well for the abrasion phenomena in the case of metals and similar solids, where the deformation is mainly plastic.

As the hard abrasive surface we have used emery papers having a mean particle diameter of 5, 10, 15, 35, 45, 70, 100 and 150 microns (grades 0000 to 3) since these represent at least approximately defined degrees of roughness down to a fineness not easily obtained by machining. The metals (copper, silver, platinum, aluminium, iron, molybdenum, tungsten) were blocks having about 3 cm.² nominal bearing area, and these were slid at about 5 cm./sec. under loads (W) of up to 2 kgm. on these emery papers. Practically identical results were obtained with the emery either dry or wet with propyl alcohol, except in the case of aluminium, which showed negligible pick-up of emery when wet, but extensive pick-up and abnormally high friction when dry.

Figs. 1 (curves a and b) and 2 show, for example in the case of copper and tungsten, the typical variation of the coefficient of friction, μ, and the wear per unit distance, M, respectively, with the mean diameter D of the emery particles.

Spurr and Newcomb[2] made similar experiments, but with loading via a lever arm on which the specimen (3/16 in. diameter rod, but probably about 0.1 cm. diameter of bearing surface) was fixed, and under which the emery paper passed on a trolley. Instead of the form of variation of μ with D shown in Fig. 1 (curves a and b), with its fall at low D to a value close to that for the metal sliding on a similar metal surface, they concluded μ increased linearly with D, the rise ($\sim$ 0.1) being due to the ploughing component[3], μ_p, which was assumed to be zero at $D = 0$, and proportional to D. In our more general conditions we have used specimens of considerable length ($\sim$ 2 cm. for curves a and b in Fig. 1) in the sliding direction. We conclude that on the finer grades of emery (D small), only in a limited front region of the specimen bearing face are there effective contacts and indentations of the emery particles into the metal. This region is estimated to be only $\sim$ 0.1 cm. for 0000 emery, but it must increase (roughly proportionally) with increasing diameter of the abrasive particles. In the remaining rear part of the face, the metal is mainly in contact with metal which has been worn away from the front specimen region and is almost completely clogging the emery in the operative bearing areas. In agreement with our quantitative theoretical estimations, we find the variation of μ with D is much less (approximately that found by Spurr and Newcomb[2]) when a shorter copper specimen (0.18 cm.) is used, as in curve a' of Fig. 1.

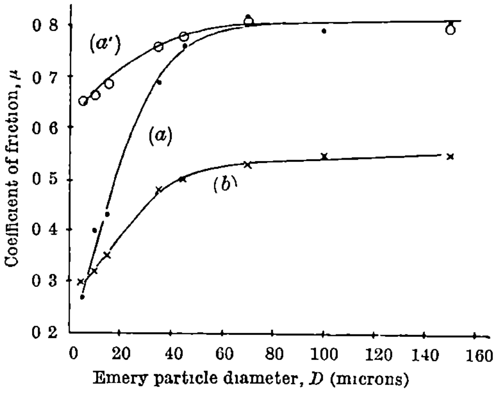

Fig. 1. μ for copper ●—●, 2 cm. specimen length, ○—○, 0.18 cm. specimen length, and tungsten ×—×, 2 cm. specimen length, sliding on various grades of emery paper

We find a corresponding form of variation of M with D (Fig. 2), also not previously described. The data of Figs. 1 and 2 also give Fig. 3, indicating an effectively linear variation of M with μ. Since M is also proportional to the load W, we have

$$M = kW(\mu - \mu_0) \qquad (1)$$

where k is a constant (different for different metals), and μ_0 is also a constant which we find is virtually identical with the coefficient of friction of two surfaces of the given metal sliding against each other at similar loading. (Experiments in this laboratory by P. V. K. Porgess, J. N. King and P. S. Dobson have shown, however, that for the non-metals graphite, molybdenum disulphide and sodium chloride, the M–μ locus is curved.)

In considering the abrasive process theoretically, we conclude that if the abrasive particles were

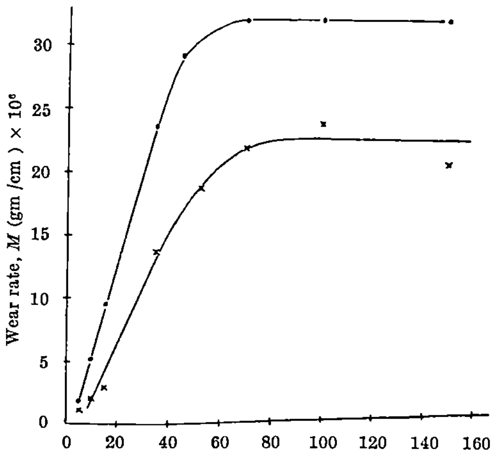

Fig. 2. Wear of 2 cm. copper and tungsten specimens on various grades of emery paper. ●—●, copper, 1 kgm. load; ×—×, tungsten, 2 kgm. load

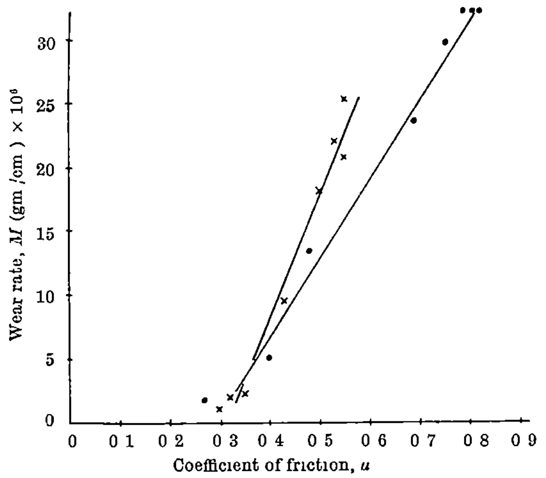

Fig 3 The linear variation of M with μ for the copper and tungsten specimens ×—×, tungsten, 2 kgm load, ●—●, copper, 1 kgm load

spherical, and all those contacting the metal shared the load equally, then μ would indeed be very small, the ploughing component μ_p being correspondingly small and of the order suggested by Spurr and Newcomb's results ($\sim$ 0 1), but that it would be practically constant, independent of D We find, in agreement with these views, that μ is, in fact, very small, $\sim$ 0 15 (and thus μ_p still smaller), for metals such as copper and silver sliding under 1–2 kgm load on a two-dimensional array of glass spheres of about 125 microns diameter ($\sim D$ for grade 2 emery) bonded on to a backing sheet (namely, "Scotchlite" reflective sheeting) Correspondingly, a negligible wear is observed in this case, although shallow, smoothly rounded grooves are formed, and little wear would be expected in view of the small inclination of the sphere surface to that of the metal near the contact, due to the low degree of indentation into the metal in the present conditions

On the other hand, for metals such as copper and silver sliding on a glass-paper or emery-paper sheet having this order of particle diameter ($\sim$ 125 microns), μ was high, $\sim$ 0 8, and practically independent of D for values of D between 50 and 150 microns We conclude (see below) that of this μ, μ_p is about 0 5, much higher than Spurr and Newcomb[2] suggested The wear rate was also high and approximately constant for D within this range The individual angular abrasive particles caused grooves in a smooth silver surface (sliding under 1 kgm load) largely by removal of more or less curved, waved or coiled strips of metal of length up to about ten times the groove width (which was $\sim$ 1/3–1/7 of D) These metal strips were often observed still integral with the metal at the front ends of the grooves The high μ and M that we observe in this range of D is thus evidently due to the emery (or glass) particles being mostly angular (as can be seen in the microscope) and not spherical

Theoretically, if n pyramidal or conical particles share the load W equally and are indented into the metal surface with their axes along the direction of the loading, then the sum of the areas of contact (between the particles and the metal) projected on to the plane normal to the loading direction must be constant and equal to W/p_m, where p_m is the maximum flow pressure of the metal Thus, n is determined by W and p_m, together with θ, the angle between the pyramid axis and one of the radial edges For square pyramids, azimuthally randomly oriented, we find that

$$\mu = \mu_p + \mu_a = (2/\pi)\,[\sqrt{2}(p'_m/p_m)\cot\theta + (s/p_m)\,(2\operatorname{cosec}^2\theta - 1)^{\frac{1}{2}}] \qquad (2)$$

and for equilateral triangular pyramids

$$\mu = \mu_p + \mu_a = (2/\pi)\,[2\ 25(p'_m/p_m)\cot\theta + 1\ 473\,(s/p_m)\,(1\ 333\operatorname{cosec}^2\theta - 1)^{\frac{1}{2}}] \qquad (3)$$

while for conical particles

$$\mu = \mu_p + \mu_a = (2/\pi)\,[(p'_m/p_m)\cot\theta + (s/p_m)\operatorname{cosec}\theta] \qquad (4)$$

where μ_a is the adhesion- or shear-component of μ, s is the tangential force required to shear unit area at the operative surface where shear occurs, and p'_m is the apparent p_m for forward ploughing against an increased pile-up of metal ahead of the moving particle We conclude that s/p_m is about 0 3, that is, about equal to the coefficient of friction of the metal (oxide) on the metal (oxide), that is, μ_0 Although $p'_m > p_m$, we can take these as approximately equal

To account for the observed maximum $\mu \sim$ 0 55 for tungsten (see Fig 1), the mean θ would thus have to be about 70° for square pyramidal particles ($2\theta = 140°$, minimum profile angle 125°) giving $\mu_p = 0\ 33$, 75° for triangular pyramidal particles (min profile angle 137°) giving $\mu_p = 0\ 37$, and 62° for cones (profile angle 124°) giving $\mu_p = 0\ 33$ This corresponds well to the sort of obtuse angularity of the particles mostly seen in the microscope This theory thus accounts well for the observed μ, which is much larger than for the case of the more shallowly indenting spheres, which approximate to cones of nearly 180° angle, that is, $\theta \sim 90°$

The constant value of μ observed at $D > 70$ microns appears, in general, to be smaller the harder the metal, for example, $\sim$ 0 78 for copper, nickel, silver and gold, 0 65 for platinum, $\sim$ 0 6 for molybdenum, chromium, iron, beryllium, and $\sim$ 0 55 for tungsten This variation is partly associated with the differing values of s/p_m (this variation is apparently small), but it appears to be mainly due to the ratio p'_m/p_m varying from 1 for the hard metals such as tungsten to $\sim$ 1 5 for the softer metals such as copper, silver and tin

The above model could be made more general by including the case of pyramids or cones having their axes inclined away from the direction of loading, but this would still be only an idealized approximation to the extremely complex actual case of irregularly shaped abrasive particles Our model shows, however, that in the absence of clogging, μ is independent of the particle size of the abrasive, and that μ_p forms the major part of the observed total μ

Now considering the wear rate, M, suppose a part, fW (where $0 < f < 1$), of the load W is supported on n identical emery particles, and the remaining load $(1 - f)\ W$ is supported on metal-to-metal contacts Let A_1 be the groove cross-sectional area (normal to the direction of sliding) A_0 being the equivalent part of this area corresponding to metal removed from the groove space but finally remaining on the specimen (for example, as the pair of piled-up ridges at the sides of the groove, and also as re-adhering wear particles) Then we conclude that

$$M = (fW\rho/p'_m)\ \alpha\ \{1 - (A_0/A_1)\}\,\mu_p \qquad (5)$$

$$= (W\rho/p'_m)\ \alpha\ \{1 - (A_0/A_1)\}\ [1 + (\mu - \mu_0)/\mu_p)^{-1}\ (\mu - \mu_0)] \qquad (6)$$

where ρ is the density of the metal, p'_m is the maximum flow pressure across A_1 to cause ploughing, and α is the fraction of the emery particles shaped and oriented favourably for producing wear particles. Comparing the observed linear form, Fig. 3 and equation (1), with this theoretical relation (6), shows that A_0/A_1 is independent of the emery particle diameter. Using an equation such as (2), (3) or (4) to express μ_p in terms of θ, equation (5) gives M directly in terms of θ and the properties of the metal, that is, ρ, p'_m, p_m, etc.

Since $M = \alpha n \rho (A_1 - A_0)$, and $nA_h = fW/p_m$, we may write as an alternative to equation (5) a more direct expression of M in terms of the properties of the metal

$$M/\rho = \alpha\ K(fW/p_m)\{1 - (A_0/A_1)\} \qquad (7)$$

$$= C\ (fW/H_D)\{1 - (A_0/A_1)\} \qquad (8)$$

where K is a constant defined as A_1 divided by the horizontal component A_h (that is, normal to the direction of loading) of the mean contact area per particle supporting the load during sliding—thus K depends on the shape of the particles; H_D is the diamond-pyramid indentation hardness number of the immediate surface region (which is very heavily work-hardened by the ploughing action of the abrasive particles); and C is a constant. Equation (8) shows that if A_0/A_1 is the same for all metals, at constant W, then

$$(M/\rho)\ H_D = \text{constant} \qquad (9)$$

Our results in Table 1 give an approximate check on the constancy of A_0/A_1 for various metals, using equation (7) to calculate $Mp_m/\rho W = \alpha K\{1 - (A_0/A_1)\}$, taking $f = 1$ and p_m = three times the ultimate tensile strength for the metal in a heavily work-hardened state (cf. $p_m \sim 90$ kgm./mm.² for copper)[3]. It is seen that $\alpha K\{1 - (A_0/A_1)\}$ is of the same order for copper, silver, platinum and iron. The small differences are probably due to the uncertainty of the value of p_m applicable to the work-hardened surface layer, and the more widely differing results for aluminium, molybdenum and tungsten seem likely to be mainly due to this uncertainty in p_m. Further circumstantial evidence of the constancy of A_0/A_1 for all pure metals is given by our interpretation of the results of Kruschov[4] (see below). The constant K depends on the shape of the abrasive particles and is ~ 0.5 in our case where $\theta \sim 60 - 70°$, and $0.5 < \alpha < 1$ from direct observation, and by consideration of the experimental $M/(\mu - \mu_0)$ values in the light of equation (6). The values of $Mp_m/\rho W$ in Table 1 thus indicate that $A_0/A_1 > 85$ per cent.

Table 1

Metal*	W	Mo	Fe	Cu	Ag	Pt	Al
Density (ρ) gm./cm.³	19	9	7.9	8.9	10.5	21.3	2.7

§ Data using emery paper flooded with propyl alcohol; all other data for dry emery paper.

Khruschov[4] showed experimentally that for all metals in the annealed state (of hardness H_{DA}), sliding on the same grade of abrasive cloth (corundum particles $\sim 80\mu$ diameter) under the same load, the volume of wear per unit length, M/ρ in our notation, is proportional to $1/H_{DA}$. He further observed, however, for various metals that M is actually practically independent of the degree of work-hardening of the initial metal, and as he concluded, this shows that the process of abrasion work-hardens the surface region of the metal (which undergoes further abrasive wear) to about the maximum possible extent, though this maximum hardness, $(H_D)_{\max}$, was not defined. Our theoretical result (8), that (for not too small distances of abrasion) M/ρ should be proportional to the reciprocal of this hardness of the abraded surface, can be considered as showing, in conjunction with Khruschov's observation of $M/\rho \propto 1/(H_{DA})$, that this $(H_D)_{\max}$ is practically proportional to (H_{DA}) for all pure metals, the factor A_0/A_1 being also the same for all pure metals.

The work described has been carried out under the terms of the extra-departmental contract between the Mechanical Engineering Research Laboratory of the Department of Scientific and Industrial Research and the Imperial College of Science and Technology, University of London.

A CAPACITANCE METHOD FOR FOLLOWING VINYL POLYMERIZATIONS INITIATED BY γ-RAYS

By G. J. K. ACRES and F. L. DALTON

Isotope Research Division, Wantage Radiation Laboratories, U.K. Atomic Energy Authority

DILATOMETRY has long been accepted as the most satisfactory method of following the course of vinyl polymerization. The change in volume as the monomer polymerizes is measured by following the fall in the level of the monomer in a capillary tube using a cathetometer. Direct optical measurement is impossible when radiation is used for initiation, and although the use of a mirror system is sometimes feasible, parallax errors tend to reduce the accuracy of the method. Also, since polymerization reactions often require several hours for their completion, a continuous recording method is clearly desirable.

A dilatometer in which the capillary is filled with mercury was developed by Schultz and Harborth[1] to obviate difficulties in following the movement of the surface of highly viscous fluids, and later modified by Burnett for use under high vacuum[2], we have adapted this dilatometer by using the falling-mercury column as one plate of a condenser, the other plate being a sheathed metal rod parallel to the capillary Polymerization is followed by measuring the change in the capacity of this condenser using a commercially available capacitance bridge and feeding the output signal to a recorder The equipment has been designed for use with the radiation sources at Wantage Radiation Laboratory these have been described in detail by Dove, Murray and Roberts[3]

The sample is prepared in a breaker-seal tube under high-vacuum conditions and sealed off Above the breaker seal a B 7 socket is attached and the sample may be connected to the body of the dilatometer by means of this joint as shown in Fig 1 The bore of tap T_1 is filled with mercury, and with T_2 open and T_1 closed the apparatus is connected to the high-vacuum line and evacuated via the B 7 cone A Reservoir R_1 is filled with mercury and tap T_2 closed T_1 is then partly opened and the mercury in R_1 allowed to spray slowly into reservoir R_2 This procedure was found to 'flash off' any small quantities of air trapped in the mercury After the mercury has run into R_2, T_2 is opened cautiously and the mercury allowed to flow into the dilatometer until it reaches the level B The seal is broken by an upward movement of the breaker C, T_2 re-opened and mercury allowed to fill the entire vessel Air is allowed into the system above A, the reaction vessel removed from the high-vacuum line and reservoir R_1 detached A capillary tube of appropriate diameter fitted with a B 7 socket and with an earthing connexion sealed through it is held by two short lengths of rubber tubing against a $\frac{1}{8}$-in steel rod covered in polythene The polythene shield prevents fluctuations due to surface adsorption of water vapour by the capillary tube The steel rod has a small metal plate attached to one end for connexion to the capacitance bridge

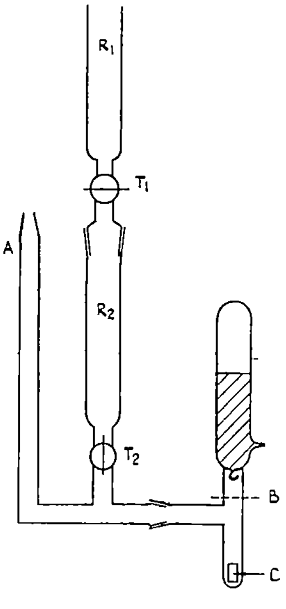

Fig. 1. Diagram of dilatometer

The capillary and fittings are shown in Fig 2 This capillary is connected by means of its B 7 socket to A picein wax is used to seal the joint By applying compressed air pressure above R_2 and opening T_2, mercury is forced through A into the capillary tube T_2 is then closed and the whole apparatus immersed in a water thermostat in the radiation source

It was found essential that the measuring capillary should be above the surface of the thermostat water, since otherwise a balance of the proximity meter could not be obtained, also, since stabilized glass tanks were not available, it was an advantage to have the capillary above the level of the thermostat tank so that the initial and final mercury-level could be accurately measured with a cathetometer

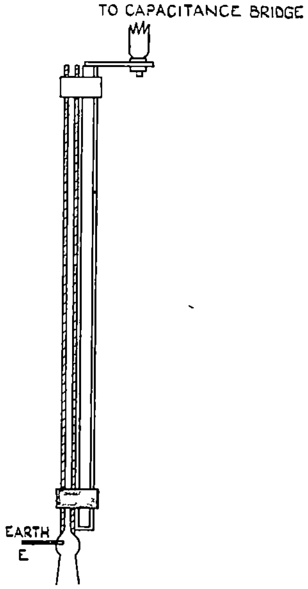

Fig 2 Capillary and electrode

Fig 3 shows the dilatometer in position The capacitance bridge used was a Fielden $PM2$ proximity meter (Fielden Electronics, Ltd, Wythenshawe, Manchester) This instrument offsets the large constant capacity of the system and measures only changes in capacity Since the length of the probe is only 6 ft the meter remains inside the radiation cell and is shielded by conventional interlocking 4-in lead bricks The sensitivity may be changed during the run if the fine sensitivity control is removed from the instrument case and mounted outside the cell This enables the first few per cent of reaction to be followed in detail at high sensitivity, if the sensitivity is then lowered an overall conversion curve may be obtained from the same sample To enable the proximity meter to be attached to a recorder, a 10-ohm resistance was put in series with the 1-m amp meter of the instrument and the voltage drop across this resistor fed to a Sunvic single-pen 10-millivolt recorder, clearly other values of this resistance may be chosen to suit any available millivolt recorder To obtain stable readings of the recorder it was found essential to earth the mercury and this was done by connecting E (Fig 2) to the earth of the mains Earthing of the thermostat tank, clamps and any other metal near the apparatus was found to be necessary A series of calibration graphs were made for various settings of the sensitivity control and various capillary diameters The dependence on sensitivity setting for a 1-mm capillary is shown in Fig 4 The use of narrower capillaries tends to lower the sensitivity of the equipment slightly In practice, initial and final mercury-levels were measured with a cathetometer in order to avoid any slight errors in the sensitivity setting

At Wantage the apparatus has been used to follow the emulsion polymerization of styrene and methylmethacrylate, and the preparation in emulsion of graft co-polymers of polystyrene and methylmethacrylate and poly-methylmethacrylate and styrene. It has also been used to follow the bulk polymerization of acrylonitrile and the graft polymerization initiated by gamma-rays of acrylonitrile on to poly-dimethylsiloxanes In use, the following precautions have been found necessary

(1) A stable power supply is required, and it is therefore advisable to supply the proximity meter from a voltage stabilizer Mains fluctuations at Wantage are exceptional, however, and this precaution may not be generally necessary (2) The proximity meter should be allowed at least 30 min to warm up before each polymerization run (3) It is essential to earth the mercury, the thermostat tank, source tube and other metal equipment near the capillary, to the instrument earth

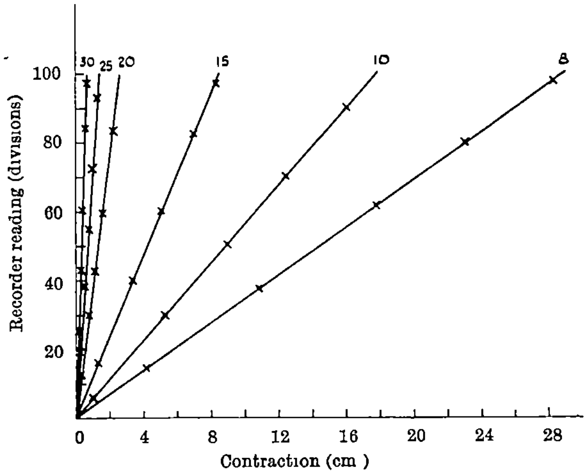

Fig 4 Calibration plot for 1 mm capillary

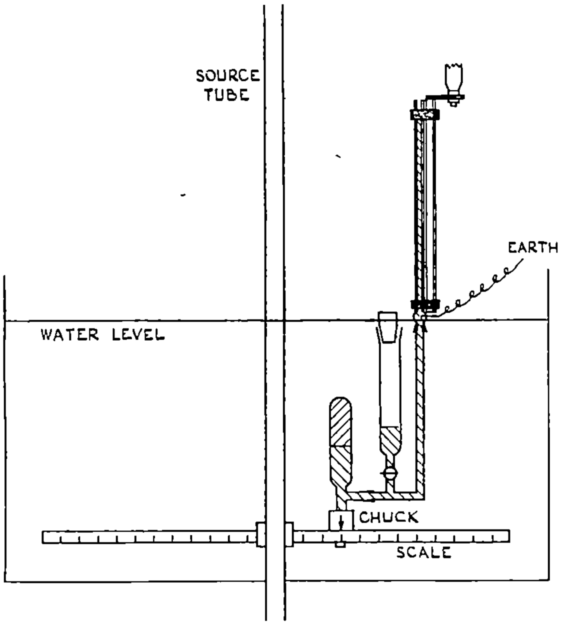

Fig 3 The dilatometer in position

The equipment has been used to measure contractions 0 6–30 cm in capillaries the diameters of which range from 2 mm to 0 5 mm The limit of 0 6 cm is imposed by the maximum sensitivity of the proximity meter Contractions greater than 30 cm have not been used in order to keep the size of the capillary small, and for contractions greater or less than these values for any given capillary, change in capillary diameter was used The limit of this process, so far as small contractions are concerned, appears to be the stability of the thermostat tank, since if the capillary is made too narrow, fluctuations due to the slight rise and fall in temperature of the tank, amounting to perhaps 0 01 or 0 02 deg C , are observed Greater sensitivity may also be obtained by increasing the diameter of the steel rod (Fig 2)

PRODUCTION OF COLICINE BY SINGLE BACTERIA

By H OZEKI, Dr B A. D STOCKER and HELÈNE DE MARGERIE
Guinness-Lister Research Unit, Lister Institute of Preventive Medicine,
London, S W I

COLICINES are bactericidal substances produced by certain strains of Enterobacteriaceae and active on others[1] Colicines in many respects resemble bacteriophages , but, unlike them, do not multiply in the cells they kill a single particle or molecule of colicine therefore does not produce a 'colony' (plaque) in the confluent growth of a sensitive strain, as does a single phage particle From the analogy with the production of phage by lysogenic strains it has been surmised that all the colicine produced by a colicinogenic culture, either spontaneously or after 'induction' by ultra-violet irradiation, is synthesized and released by a fraction of the bacterial population, and that these cells are in consequence non-viable No direct test of this hypothesis has been possible because colicine production has hitherto been tested only by observation on the antibiotic activity of mass cultures We have now demonstrated the release of colicine by individual bacteria. (i) through the production by single bacteria of small clear spots in the confluent growth of a colicine-sensitive strain , (2) by the bactericidal action of products released into micro-drops of broth by single colicinogenic bacteria isolated by micro-manipulator. The results obtained by these techniques support the above hypothesis.

The colicinogenic strains used were derivatives of *Salmonella typhimurium* strain *LT2* made colicinogenic by growth in mixed culture with colicinogenic *Escherichia coli* or *Shigella* strains[1], or by phage-mediated transduction[2]. The colicine-sensitive indicator strains were *E. coli* strain φ[3] and antibiotic-resistant mutants derived from it.

To demonstrate the clear spots caused by the colicine released by single bacteria we used a modification of the soft agar layer method used in phage work. 3 ml. of soft agar (0.35 per cent) seeded with about 10^8 cells of the indicator strain and about 10^4 cells of a young broth culture of *S. typhimurium* producing colicine *E*2[4] were poured on to a nutrient agar plate; after 5 hr. incubation at 37° about 100 small clear spots, 0.2–0.8 mm. in diameter, were visible in the confluent growth of the indicator strain. No such spots were produced by cells of a non-colicinogenic *Salmonella* strain, nor with an indicator strain resistant to colicines of the *E* group. Colicine *E*2 is destroyed by trypsin; crystalline trypsin (200 μgm./ml.) in the soft agar prevented the appearance of clearings. Although the spots looked like phage plaques, no lysis was observed when they were cut out and tested on a fresh plate of indicator bacteria.

It thus appeared that the clear spots resulted from the production of colicine *E*2, either by the colicinogenic bacteria inoculated, or, perhaps, by their descendants. The following results show that a clear spot can be produced by the colicine synthesized and liberated by a single bacterium.

Colicinogenic bacteria when plated with a streptomycin-resistant indicator in soft agar containing sufficient streptomycin to prevent their growth still produced some clear spots. Similar results were obtained with chloramphenicol. Furthermore, some clear spots were produced even when the colicinogenic cells had been killed by treatment with chloroform for 5 min. at 37° before inoculation. The number of clear spots produced in the presence or absence of streptomycin was directly proportional (about 1 per cent) to the number of cells of the colicinogenic strain incorporated into the soft agar layer. Blendor treatment, sufficient to break up any cell clumps, applied to the colicinogenic culture just before its inoculation into the soft agar, did not affect the number of clear spots produced. The number of clear spots appearing in the presence of streptomycin was 10- to 100-fold less than without it; this suggests that most of the clear spots formed in the absence of streptomycin are produced by bacteria which synthesize colicine on the plate, but that there are a few cells in the culture each of which at the time of plating already contains enough colicine to produce a clearing.

Clear spots were produced, either in the presence or absence of streptomycin, even when the colicinogenic cells had been grown in broth containing trypsin, provided the trypsin was removed by washing, or neutralized by soy-bean trypsin inhibitor, at the time of plating. As all free colicine in the inoculum culture was destroyed by the trypsin, the colicine causing a clear spot cannot have been adsorbed from solution by a cell of the inoculum culture, and released later, a hypothesis proposed by Frédéricq[5] to explain the small plaque-like clearings he observed when dilutions of a colicinogenic culture killed with chloroform were plated with a colicine-sensitive indicator strain; it now seems probable that these clearings, like those here reported, resulted from production of colicine by single bacteria.

In certain colicinogenic strains, colicine production is inducible by ultra-violet irradiation[1]. The number of clear spots produced by a strain colicinogenic for *E*2 was much increased by irradiation before plating; if cells irradiated for a time which reduced the viable count by about 70 per cent were plated in a streptomycin soft-agar layer 90 min. later, the number of clear spots which appeared was half or more of the total number of colicinogenic bacteria inoculated, determined in a counting chamber.

We propose the term 'lacuna' for the clear spots produced by the colicine released by a single bacterium, in distinction from a phage 'plaque'. The soft agar of an area 0.8 mm. in diameter contains about 6,500 colicine-sensitive bacteria at the time of inoculation; the presence of lacunæ of this size indicates that some colicinogenic bacteria liberate at least 6,500 bactericidal particles of colicine *E*2.

The production of colicine by individual bacteria has also been demonstrated by micromanipulative isolation. Cells of the colicine-sensitive indicator strain grew as non-motile filaments, easily distinguishable from the short motile cells of *Salmonella typhimurium*. Cells of the indicator strain inoculated into droplets of broth containing colicine *E*2 failed to multiply, and became abnormal in appearance, showing alternate bright and dim segments when examined by low-power dark-ground microscopy; cells of a colicine-*E*2-resistant mutant of the indicator strain multiplied normally in such droplets. To test the production of colicine by individual bacteria, a strain of *S. typhimurium* colicinogenic for colicine *E*2 was 'induced' by ultra-violet light and incubated for 30 min. at 37° in broth, containing trypsin (500 μgm./ml.) to inactivate extra-cellular colicine. The irradiated cell suspension was then introduced into a micromanipulation chamber, and each of a series of droplets of broth with trypsin inhibitor 2 mgm./ml. was inoculated with a single bacterium from the suspension; volumes of the suspension not containing any cells were added to control droplets. 2 hr. later the colicinogenic bacterium had multiplied in about 20 per cent of the droplets; in the remainder it had not multiplied but was still visible. The proportion of single bacteria able to multiply in the micro-drops agreed well with the survival-rate of the irradiated suspension inferred from the ratio of viable and total counts. Three to twenty cells of the indicator strain were then added to each droplet. In about 60 per cent of the droplets in which the colicinogenic bacterium had failed to multiply the indicator bacteria added later did not multiply and instead developed the characteristic abnormal appearance. In the remaining 40 per cent the indicator bacteria multiplied normally, as they did also in the control droplets which had received medium, but no bacterium, from the suspension of irradiated colicinogenic bacteria. In droplets in which the colicinogenic bacterium had multiplied, the indicator bacteria at first multiplied, showing absence of colicine, but later ceased to grow, presumably as a result of colicine being released by one or more of the large population of colicinogenic bacteria then present. About 50 per cent of the individual bacteria tested were shown by this method to release colicine; in platings from the same irradiated suspension the ratio of the number of clear spots to the total number of bacteria was about 6 10

The micromanipulation experiments described above indicated that all or nearly all the cells of an irradiated culture which release colicine *E*2 are non-viable To see whether this was also so for the spontaneous production of colicine *E*2, about 1,000 cells of a chloramphenicol-sensitive colicinogenic strain were plated in a soft agar layer of a defined medium containing chloramphenicol, together with a chloramphenicol-resistant indicator strain , the latter was nutritionally exacting, so that it could multiply to only a small extent in the defined medium provided After 5 hr incubation, twelve lacunæ were visible in the thin confluent growth of the indicator After overnight incubation about 1,000 small colonies of the nutritionally less exacting colicinogenic strain appeared, the chloramphenicol concentration having fallen, by diffusion into the base layer of agar, below the level required to inhibit its growth No colonies developed at the centres of the twelve lacunæ marked earlier It is concluded that the bacteria which produced these clearings by releasing colicine were unable to multiply

The production of lacunæ has been used for a number of other investigations which will be reported in detail elsewhere *Salmonella typhimurium* strains producing colicines *I*, *B*, *K* and *E*1 produce lacunæ, of sizes about the same as with colicine *E*2 When overnight broth cultures were tested in soft agar containing streptomycin the numbers of lacunæ produced per million bacteria plated were approximately colicine *E*2, 1,000 , *I*, 0 2 , *B*, 200 , *K*, 300 , and *E*1, 1,000 The ratio varied in cultures of different ages , for example, it increased 10-fold when an overnight culture of a strain producing colicine *E*2 was diluted in broth and incubated for 1 hr at 37° After ultra-violet irradiation the fraction of bacteria producing lacunæ increased to about 0 5 in strains producing colicines *E*1 and *E*2 , no increase was detected in a strain producing colicine *I*

We thank Prof P Frédéricq for the provision of colicinogenic strains

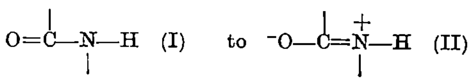
PERMANENT SET, SUPERCONTRACTION, AND UREA-BISULPHITE SOLUBILITY—THE PROTON-TRANSFER NATURE OF SOME CHANGES IN KERATIN AND THE ANALOGY WITH MUSCLE CONTRACTION

By Dr P T SPEAKMAN

Department of Textile Industries, University of Leeds

DURING the reaction of cystine residues in keratin with OH⁻ ions, sodium bisulphite, etc , the proportion of



$$\mathrm{O{=}\overset{|}{C}{-}\underset{|}{N}{-}H}\ \text{(I)}\quad\text{to}\quad \mathrm{{}^{-}O{-}\overset{|}{C}{=}\underset{|}{\overset{+}{N}}{-}H}\ \text{(II)}$$

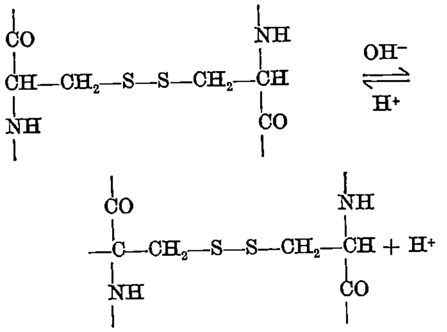
contributing to the resonance hybrid of the peptide groups hydrogen-bonded to each other in the protein network, and eventually to a carbonyl oxygen atom of the cystine residue, can alter An increase in the proportion of II (that is, an increase in the negative charge on the oxygen atom) will affect the strength of the hydrogen bonds between peptide groups electrostatically , also, it can be shown that an increase in the strength of the individual hydrogen bonds will follow as more peptide groups are attracted into the co-operating, hydrogen-bonded system The stability of permanently set keratin, and of keratin treated with alkali with a decreased solubility in urea-bisulphite solutions, seems likely to be caused by an increase in the strength of the hydrogen bonds between protein chains, caused in this way The analogy between muscle contraction and supercontraction of keratin suggests a mechanism of contraction of muscles containing sulphur in which disorientation and contraction of the muscle follows a weakening of the hydrogen bonds between peptide groups by reagents which react with sulphydryl groups Re-orientation of the muscle would follow an increase in the charge on the oxygen atoms of the peptide groups during the reverse reaction

In some early experiments on permanent set[1], a keratin fibre was extended in water and treated under tension with, for example, steam, boiling buffer solutions, or sodium sulphite solution The treated fibre was immersed without tension for an arbitrary period (1 hr) in boiling water, and if the fibre was to some extent stabilized in its extended form and its length remained greater than the initial length then it was said to be permanently set , if it was less, supercontraction had occurred Cross-linkages between the keratin chains are broken by the treatments, thus allowing the chains to rearrange in the stretched fibres If no new cross-linkages are formed then a change in the arrangement of the uncross-linked protein chains after immersion in boiling water causes supercontraction If new cross-linkages are formed in the treatments, then the chains are to some extent held in their positions in the extended fibre, thus causing permanent set A chemical treatment which decreases the solubility of keratin in urea-bisulphite solutions[2] is similarly most plausibly explained by new, resistant linkages between protein chains

Breaking of cystine disulphide bonds is an essential preliminary to permanent set in wool, but work in Australia on fibres containing reduced and alkylated cystine residues[3], and on the birefringence and contraction in lithium bromide solutions of set fibres[4], shows that it is an over-simplification to suggest that permanent set is entirely due to new covalent cross-linkages formed after reduction or hydrolysis of the cystine residues Two cross-linkages which have been directly confirmed in set fibres are lanthionine, thioether linkages, and re-formed cystine linkages, but these are not sufficient to account for the stability of permanently set fibres Some set remains after the fibres are treated without tension in boiling 5 per cent sodium bisulphite solution which will break re-formed cystine linkages, and Kessler and Zahn[5] point out that lanthionine derivatives are scarcely more stable than cystine towards the plumbite test for sulphur in acid or alkali, for example Lanthionine derivatives are also unstable in the urea-bisulphite reagent

The decreased solubility of alkali-treated wool in urea-bisulphite solutions cannot be explained by the formation of lanthionine cross-linkages or any other linkages derived wholly or in part from cystine, because it has been shown by Lees and Elsworth[2] and by Kessler and Zahn[5] that large changes in urea-bisulphite solubility occur before any change in the cystine content of the wool

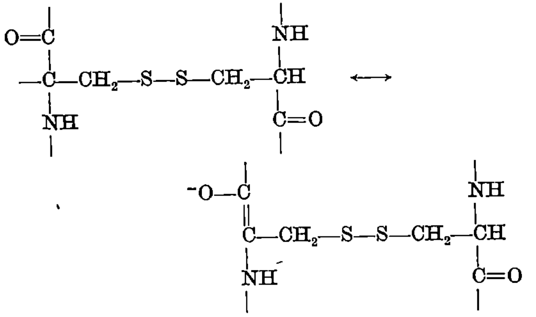
The work of Swan[6] with α, α′-dimethylcystine has shown that the first step in the alkaline hydrolysis of cystine is probably the ionization of a proton from an α-carbon atom



$$\underset{NH}{\overset{CO}{CH}}-CH_2-S-S-CH_2-\underset{CO}{\overset{NH}{CH}} \underset{H^+}{\overset{OH^-}{\rightleftharpoons}}$$

$$-\underset{NH}{\overset{CO}{C}}-CH_2-S-S-CH_2-\underset{CO}{\overset{NH}{CH}} + H^+$$

The negative charge on the cystine molecules will be divided between the α-carbon atom and the carbonyl oxygen atom, where it is inherently more stable, in a resonance hybrid



$$-\underset{NH}{\overset{O=C}{C}}-CH_2-S-S-CH_2-\underset{C=O}{\overset{NH}{CH}} \longleftrightarrow$$

$$\underset{NH}{\overset{^{-}O-C}{\overset{\|}{C}}}-CH_2-S-S-CH_2-\underset{C=O}{\overset{NH}{CH}}$$

If now the cystine residue is considered as part of a hydrogen-bonded protein network then the increased negative charge on the carbonyl oxygen atom following alkali treatment will induce a greater separation of charge on the co-operating, hydrogen-bonded peptide groups If proton transfer takes place between neighbouring peptide groups, these will change from the predominantly keto or lactam form to a predominantly enol or lactim form

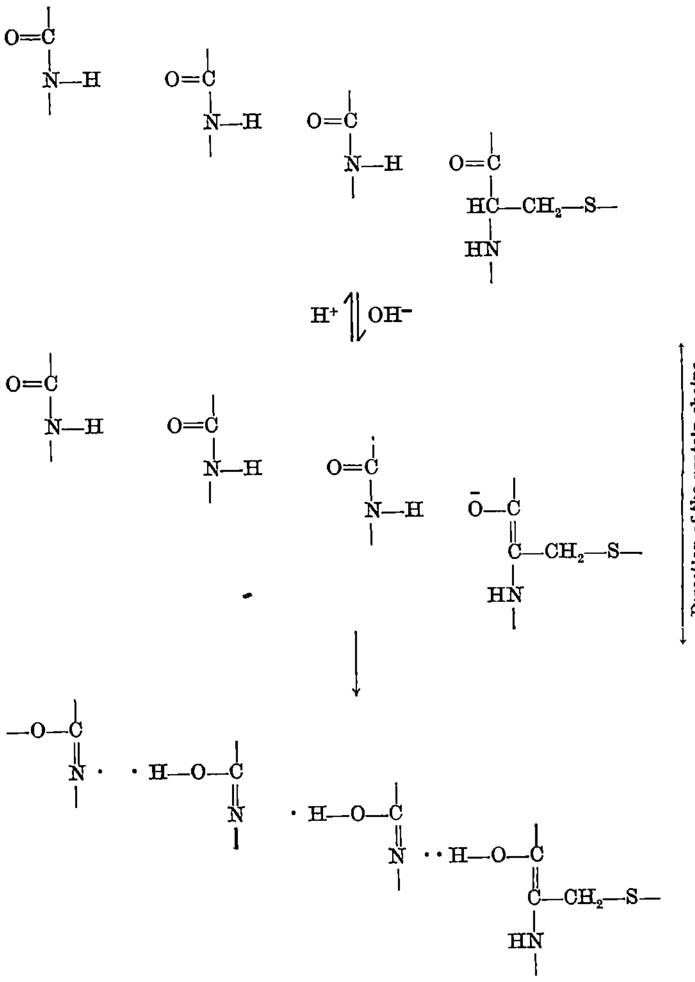


Fig 1

X-ray diffraction photographs show that an extended keratin fibre, treated with a setting reagent such as steam or boiling alkaline buffer solutions which will hydrolyse cystine residues, is set in the β, extended-chain, form, whereas an extended but untreated fibre returns slowly in water to the original α-helical form It is tempting, therefore, to suggest that in unset β-keratin the main protein-chain peptide groups are in the keto form, —CO—NH—, and in set β-keratin they are in the enol form, —C(OH) = N—, and that the hydrogen bonds in the enol form are stronger since set β-keratin is more stable The evidence for and against this theory follows

Evidence in favour (1) Only small shifts in the infra-red absorption frequency at the hydrogen-bonded NH stretching frequency of approximately 3,300 cm^{-1} are observed when set β-keratin is compared with α-keratin or other β-keratins[7], but 3,300 cm^{-1} is well within the range of OH stretching frequencies[8] when they are hydrogen-bonded thus O—H N Badger and Bauer[9] have pointed out that the difference in the frequency between the hydrogen-bonded and non-hydrogen-bonded OH stretching vibrations is related to the energy of the hydrogen bond The difference between the non-hydrogen-bonded OH frequency (3 700 cm^{-1}) and 3,300 cm^{-1} would indicate a fairly strong hydrogen bond which might account for the greater stability of set β-keratin compared with unset β-keratin

(2) The bond-angles and bond-lengths of Pauling's model of β-keratin[10] are deduced from the lengths and angles in amino-acid and simple peptide crystals These are in the keto form, but it might be equally possible to construct a model of β-keratin which would be compatible with the observed X-ray spacings from the dimensions and angles of the enol forms of peptides were these available In their absence, an approximate calculation can be made from Pauling's keto model In this model the CN bonds are inclined at an angle of 25° to the direction of the protein chain and have 40 per cent double-bond character If 60–70 per cent double-bond character is assumed in the enol form, this implies a bond 0 03–0 04 A shorter in length, so that the protein chain must shorten approximately 0 035 cos 25° A for each peptide unit = 0 032A The variation in length which would be caused by a change from keto to enol form might just be detectable experimentally assuming, as is likely, that no great change in bond-angles occurs and that the nitrogen atom remains sp^2 hybridized

Evidence against (1) Like the infra-red absorption at 3,300 cm $^{-1}$, the absorptions at 1,650 cm $^{-1}$ and 1,550 cm $^{-1}$ show only small shifts (25–30 cm $^{-1}$) when set β-keratin is compared with α-keratin and other β-keratins Fraser and Price[11], using Pauling's fractional bond orders, attribute the 1,650 cm $^{-1}$ absorption to an interaction between CO and CN frequencies The absorption at 1,550 cm $^{-1}$ is attributed to a coupling between an $\overset{\mathrm{N-C}}{\underset{\mathrm{O}}{\diagdown}}$ mode and an NH bending frequency By choosing the appropriate CO and CN bond orders it might be possible to devise an enolic NCO group to account for the 1,650 cm $^{-1}$ absorption, but it would seem to be stretching coincidence to suggest that one of the modes of the new NCO group would couple with an OH bending frequency to account for the 1,550 cm $^{-1}$ absorption

(2) A change from keto to enol form of the peptide groups would alter the length of the CO bond, and a further coincidence would be required since the protein backbone spacing in the β-form, which is related to the length of the interchain hydrogen bonds, NH . OC or N HOC, does not alter

(3) Lastly, Huckel[12] points out that the enolic forms of ketones are well known and that the keto/enol ratios can often be determined experimentally, but that no case is known where the enol or lactim form of an amide, *R*C(OH) = N*R*′, can be estimated or even shown unequivocally to exist Theoretical reasons are adduced to explain this in keto-enol tautomerism no movement of electrons can occur without proton transfer, in lactam–lactim tautomerism electrons can move in the group without proton transfer because of the lone pair on the nitrogen atom It may be that there is no energy barrier between the two forms so that the less stable form cannot exist Work on other hydrogen bonds has shown, for example, that the activation energy of the change O—H O → O H—O can be small or non-existent[13]

Thus, the possibility that in set β-keratin the peptide groups are in the enol form must be rejected Nevertheless, when cystine residues are in equilibrium with alkaline solution each must spend some fraction of its time in the ionized form before the dissociation postulated by Swan[6] takes place to an α-aminoacrylic acid residue and $^{-}$SSCH$_2$CHCONH— If the carbonyl oxygen atom of an ionized cystine residue is part of a hydrogen-bonded network its increased negative charge will have two effects, these are related to the bond-breaking and bond re-formation reactions in the original theories of supercontraction and permanent set

(1) An increase in the negative charge on the carbonyl oxygen atom of a cystine residue will induce a greater separation of charge in a peptide group hydrogen-bonded to it, increasing the positive charge on the nitrogen atom and the negative charge on the oxygen atom Similar charges will be induced in a second peptide group hydrogen-bonded to the first, and so on

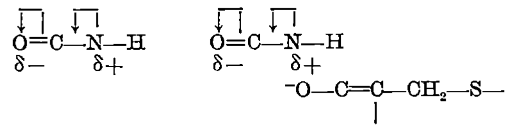

Fig 2

It is impossible to say from theoretical considerations whether these changes will increase or decrease the strength of the hydrogen bonds[8], but in the reactions of keratin considered here the hydrogen bonds appear to be weakened

(2) An induced, increased negative charge on the ultimate peptide carbonyl oxygen atom will attract further peptide groups into the hydrogen-bonded series of peptide groups which, in β-keratin, runs at right angles to the protein chains (Fig 1) and, in α-keratin, down the helices (Fig 3) Thus, with the aid of kinetic energy from the setting solutions, further peptide groups will be oriented into the α-helix of unextended keratin or the parallel chains of extended β-keratin An increase in the proportion of amino-acid residues in α-helices has been shown[14] to increase the optical rotation of a protein, so that the effect may be detectable using thin films sectioned from treated, unextended keratin fibres When

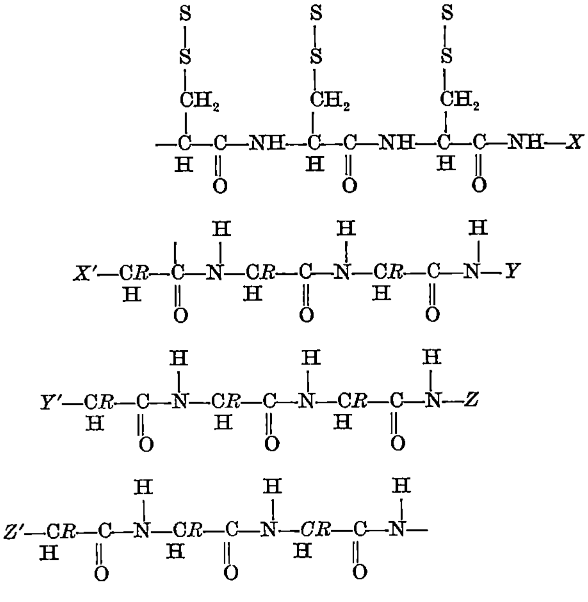

Fig 3 Diagram of the α-helical form of keratin (in the helix *X* is joined to *X*′, *Y* to *Y*′, etc) showing how three cystine residues can influence all the hydrogen bonds of the helix

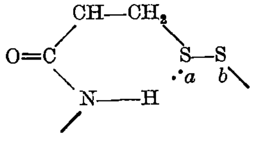
extended fibres are set, the X-ray diffraction photograph of set β-keratin, compared with unset β-keratin[15], shows a sharpening of the backbone reflexion, confirming the orientation of more protein chains into the strict β configuration. Davies, Evans and Lumley Jones[16], using methyl acetamide in carbon tetrachloride, have shown that the shift in the hydrogen-bonded NH vibration infra-red absorption frequency away from the non-hydrogen-bonded NH vibration frequency is increased from approximately 120 cm^{-1} to 190 cm^{-1} as the concentration of amide is increased. The shift can be attributed to an increase in the number of amide groups hydrogen-bonded together in each linear aggregate. The difference between the absorption frequencies of the NH vibration in non-bonded and hydrogen-bonded amide groups is proportional to the energy of the hydrogen bond, and therefore in the experiments of Davies, Evans and Lumley Jones the energy has been increased 60 per cent by increasing the number of co-operating hydrogen-bonded amide groups in each linear aggregate. Thus the stability of a hydrogen-bonded protein structure can be increased by bringing more peptide groups into the co-operating hydrogen-bonded system. If it becomes possible to examine the infra-red spectrum of unset β-keratin the NH vibration frequency should show a smaller shift from the non-hydrogen-bonded NH frequency than the NH vibration frequency in set β-keratin where, according to the present theory, the protein chains are oriented so that there are more co-operating peptide groups in each hydrogen-bonded series.

If the hydrolysis of cystine in steam, like the hydrolysis by OH$^-$ ions, involves ionization of a proton at the α-carbon atom, then the observed facts of steam setting are readily explained. At first, in the extended fibre, the hydrogen bonds are weakened by the increased polarization of the peptide groups. Immersion of the fibre without tension in boiling water after up to 15 minutes in steam causes supercontraction. Longer treatment in steam allows further orientation of the protein chains, and more co-operating peptide groups increase the strength of the individual hydrogen bonds, thus causing permanent set[15]. Treatment of extended keratin fibres in boiling borate buffer solutions[1] (*p*H 9·2) for 30 min. causes permanent set, orientation strengthening the individual hydrogen bonds. Less drastic treatment with phosphate buffers from *p*H 8 to 10 for 1 hr. at 50° C.[17] or 20 per cent potassium hydroxide solution at 28·5° C. for 3 min.[18] causes weakening of the hydrogen bonds by increased polarization of the peptide groups, without sufficient subsequent orientation to strengthen the hydrogen bonds, and thus supercontraction occurs under these conditions.

Swan[6] has shown that the hydrogen atom attached to the α-carbon of cystine is not involved in the reduction of cysteine by sodium sulphite. However, sulphur can take part in hydrogen bonding[19], and the most plausible hydrogen bond in cystine residues would seem to be:



The approach of a negative ion, SO$_3^{2-}$ or HSO$_3^-$, to sulphur atom *b* would induce a positive charge on *b* and a negative charge on *a*. In turn, the polarity of the peptide group would be increased. The negative charge on *a* will be further increased if the cysteine residue formed in the reduction is ionized, and in fact the setting reaction does appear to be catalysed by alkali[17]:

$$R\text{—}\underset{a}{S}\text{—}\underset{b}{S}\text{—}R + SO_3^{--} \rightarrow R\text{—}\underset{a}{S}^- + {}^-O_3S\text{—}\underset{b}{S}\text{—}R$$

The changes in the polarization of the peptide group and other peptide groups hydrogen-bonded to it will cause immediate weakening and eventual strengthening of the hydrogen bonds as in steam-setting and setting in alkaline solutions.

During the synaeresis of actomyosin after adding adenosine triphosphate, the X-ray diffraction pattern shows in certain conditions the appearance of a faint 'cross-β' reflexion which is typical of supercontracted keratin[20]. This suggests that there may be some similarity between the contraction of components of muscle containing sulphur and keratin supercontraction. Reaction with sulphydryl groups of muscle protein could alter the stability of the hydrogen-bonded network so that the chemical energy from a reversible, high standard free energy transphosphorylation, for example, liberated as kinetic energy, would cause disorientation of the protein structure and contraction. Then the reverse phosphorylation might induce negative charges on the peptide carbonyl oxygen atom and thus re-orient the muscle component into its original α-helical form.

This theory of permanent set, supercontraction, and urea-bisulphite solubility of keratin is put forward to explain those experimental facts[2-5] not fully explained by the early theories of permanent set[1,15]. There is no doubt, however, that all the chemical forces—covalent, electrovalent, van der Waals, and not merely hydrogen bonding—are involved in the three experimental phenomena considered.

I am grateful to Prof. W. T. Astbury for many suggestions during helpful discussions of this work.

INACTIVATION OF SOME ANIMAL VIRUSES BY HYDROXYLAMINE AND THE STRUCTURE OF RIBONUCLEIC ACID

By Dr RICHARD M FRANKLIN and Dr EBERHARD WECKER

Max-Planck-Institut fur Virusforschung, Tubingen, Germany

In the course of some studies on factors which might stabilize infectious ribonucleic acid isolated with phenol from animal viruses, it was found that hydroxylamine inactivates the infectious ribonucleic acid extracted from mouse encephalomyelitis virus (Table 1). In addition, several animal viruses, all of which contain ribonucleic acid, proved to be sensitive to hydroxylamine (Table 1).

Hydroxylamine may act on animal viruses by affecting (1) viral protein, (2) viral ribonucleic acid, or (3) both viral components. Several types of experiment were performed in order to locate the site of action of hydroxylamine. In the first type of experiment, mouse encephalomyelitis virus was treated with hydroxylamine and then ribonucleic acid was extracted. If hydroxylamine had reacted with the ribonucleic acid of the virus, then the extracted ribonucleic acid should be non-infectious. This type of experiment must be distinguished from that described in Table 1, where infectious nucleic acid is first extracted from virus particles and then treated with hydroxylamine. The experiments were carried out as follows. Mouse encephalomyelitis virus was incubated in 1 *M* hydroxylamine at 22° C and *p*H 7. A control preparation, containing no hydroxylamine, was incubated under the same conditions. The virus preparations were treated for various periods of time in the individual experiments. After dialysis of both samples, aliquots were assayed for virus infectivity to determine the virus survival ratio. The same samples were treated with phenol at 42° C to extract ribonucleic acid[1,2]. Infectivity of ribonucleic acid was titrated by intracerebral inoculation in mice. The ratio of the infectivities of ribonucleic acid extracted from treated virus to that extracted from control virus should be the same as the virus survival ratio if hydroxylamine inactivates the virus only by alteration of viral ribonucleic acid. Highly variable results were obtained, but the average virus survival ratio was only four times higher than the average survival ratio of the extracted ribonucleic acid. Considering the many manipulations involved in these experiments, the results indicate that hydroxylamine acts on mouse encephalomyelitis virus by altering the viral ribonucleic acid. This conclusion is also supported by the fact that mouse encephalomyelitis virus is inactivated at a rate comparable to that of infectious ribonucleic acid isolated from the virus (Table 1).

The second type of experiment to locate the site of action of hydroxylamine tested the effect of this compound on several activities of viral protein. A mouse encephalomyelitis virus preparation, inactivated by treatment with 1 *M* hydroxylamine at 22° C for 24 hr and then dialysed for 24 hr, had the same complement-fixing activity against a rabbit antiserum to mouse encephalomyelitis virus as a control preparation. Thus treatment of mouse encephalomyelitis virus with hydroxylamine results in an alteration of the infectivity of the ribonucleic acid without major alterations in the serological properties of the protein. In order to study the effect of hydroxylamine on other proteins of animal viruses, a fowl plague virus concentrate was treated with 1 *M* hydroxylamine for 24 hr, resulting in complete inactivation. After 24 hr dialysis, the hæmagglutinating activity was the same as that of a control. Further, the enzymatic activity of the virus, measured by elution from red blood cells at 37° C, was identical in treated and control preparations. The complement-fixing ability of the treated preparations was the same as that of the control, when measured with anti-fowl plague serum. Hence, as in the case of mouse encephalomyelitis virus, hydroxylamine had not caused any detectable changes in the viral protein, at least in the peripheral protein.

Table 1. THE INACTIVATION OF SOME ANIMAL VIRUSES AND ANIMAL VIRUS RIBONUCLEIC ACID BY HYDROXYLAMINE

A 4 *M* solution of hydroxylamine hydrochloride is adjusted to neutral *p*H by mixing with an equal part of 14 per cent sodium hydroxide. This solution is mixed with an equal part of infectious material and incubated for 15 min at 22° C. For the inactivation of viruses the reaction is stopped by 1 : 5 dilution in phosphate buffered saline (ref. 16) at 4° C, and excess hydroxylamine is removed by dialysis against phosphate buffered saline for 24 hr. For inactivation of infectious ribonucleic acid, the reaction is stopped and hydroxylamine removed by precipitation of the ribonucleic acid with alcohol. The virus infectivity was measured by plaque test (ref. 17) and the infectivity of ribonucleic acid from mouse encephalomyelitis virus was titrated by intracerebral inoculation in mice (ref. 1)

Infectious material	Survival ratio*
Infectious ribonucleic acid from mouse encephalomyelitis virus	2.6×10^{-2} 1.8×10^{-2}
Mouse encephalomyelitis virus	2×10^{-2}
Fowl plague virus	2×10^{-3}
Swine influenza	2×10^{-4}
Western equine encephalomyelitis virus	3×10^{-4}

* Titre of treated/titre of control

Hydroxylamine also inactivates certain bacterial viruses, but the action in this case is on a protein component, probably resulting in the rupture of thiol ester bonds in the protein of the tail fibres[3]. The activation energy of this process[3] is approximately 19 kcal./mole. To contrast this with the inactivation by hydroxylamine of animal viruses, the activation energy for the inactivation of western equine encephalomyelitis virus was determined over the temperature range 20–44° C. A value of approximately 4 kcal./mole was found. The difference observed in the activation energies for the inactivation of bacterial viruses and western equine encephalomyelitis virus indicates that different chemical processes may be involved in the two cases.

(*Note added in proof* The activation energy for inactivation of mouse encephalomyelitis virus is 15 6 kcal /mole Since mouse encephalomyelitis virus and mouse encephalomyelitis ribonucleic acid are inactivated at the same rate, this must be the energy associated with the reaction of ribonucleic acid with hydroxylamine This is similar to the energy for splitting thiol-ester bonds and may further suggest that an ester bond is split from ribonucleic acid by hydroxylamine The previously determined activation energy for inactivation of western equine encephalomyelitis virus may then represent a secondary reaction, perhaps an alteration of viral lipid)

A direct attack on the nature of the reaction of hydroxylamine with ribonucleic acid gave little positive information 'Model' ribonucleic acid was prepared from rat liver and calf liver by extraction with phenol at 4° C , using phosphate–citrate buffer at pH 5 in order to prevent the simultaneous extraction of deoxyribonucleic acid After alcohol precipitation, followed by precipitation with 1 *M* sodium chloride, the nucleic acid obtained consists of a two-component system with molecular weights $\sim 2 \times 10^6$ and $\sim 6 \times 10^5$, respectively (cf ref 4) This ribonucleic acid was treated with hydroxylamine for 24 hr or 48 hr and excess hydroxylamine was removed by repeated alcohol precipitation of the ribonucleic acid There was no degradation of ribonucleic acid, as revealed by analytical ultracentrifugation Further, paper chromatographic and paper electrophoretic studies of the products of alkaline and acid hydrolysis showed no differences from those of untreated ribonucleic acid Thus hydroxylamine does not seem to split the phosphate–sugar backbone of ribonucleic acid or alter any of the bases If one of these processes was responsible for the inactivation of infectious ribonucleic acid, which has a $1/e$ value of 3 7 min , meaning that an average of one such inactivating event has occurred in each molecule in 3 7 min , then approximately 400 such inactivating events would occur per molecule in 24 hr The failure to detect any changes after 24–48 hr with the methods used is strong evidence that inactivation did not occur by either of the above-mentioned processes As a comparative example, the oxidative deamination of adenine, guanine and cytosine in ribonucleic acid by nitrous acid can be demonstrated chromatographically after a reaction time of about 20 hr [5]

Recent studies on the chemistry of protein synthesis have shown that amino-acids are bound to a ribonucleic acid of low molecular weight (soluble-ribonucleic acid) before being coupled together in a polypeptide chain[6,7] The amino-acid is bonded to soluble ribonucleic acid at a 2′ or 3′ hydroxy-position of the terminal ribose and this amino acyl ester bond can be split by hydroxylamine[8] It could be that a similar structure exists in some forms of high molecular weight ribonucleic acid and that such a structure is essential for the biological activity of ribonucleic acid in those cases It would be difficult, however, to demonstrate the existence of an amino acyl ester in nucleic acid of molecular weight $\sim 2 \times 10^6$ since, by weight, the amino-acid represents ~ 1 part in 10^4 of nucleic acid Therefore, this hypothesis must be investigated by some indirect approach

One such approach is a comparison of the stability of the amino acyl-soluble-ribonucleic acid bond with that of the infectivity of ribonucleic acid from mouse encephalomyelitis virus (Table 2) The stability of infectious ribonucleic acid in the pH range 5–7 and the instability at pH 8 6 correspond to the pH stability of an amino acyl ester bond Control experiments on the degradation at pH 8 6 of 'model' ribonucleic acid from calf liver, measured by alteration of viscosity during a 48-hr period, showed that inactivation of infectious ribonucleic acid at pH 8 6 could not be due to alkaline hydrolysis of the phosphate–sugar backbone Hydroxylamine inactivation of ribonucleic acid from mouse encephalomyelitis virus proceeds more rapidly at pH 7 than at pH 5 5 and this is also true for hydroxylamine splitting of the amino acyl ester bond to soluble-ribonucleic acid[8] In contrast, the reaction of hydroxylamine with activated amino-acids (mixed anhydrides in which the carboxyl group of the amino-acid is phosphorylated)[9] occurs equally well[8] at pH 5 5 and pH 7 0 Therefore, if an amino-acid or related compound is linked to the ribonucleic acid of certain viruses, as suggested by these experiments, then the bond should be similar to that between amino-acids and soluble-ribonucleic acid (ester) rather than to that in activated amino-acids (mixed anhydride)

Table 2 A COMPARISON OF THE STABILITY OF AN INFECTIOUS RIBONUCLEIC ACID FROM MOUSE ENCEPHALOMYELITIS VIRUS AND THE AMINO ACYL ESTER BOND TO SOLUBLE-RIBONUCLEIC ACID

Infectious ribonucleic acid	Amino acyl ester soluble-ribonucleic acid bond
Stable at pH 5 60° for at least 10 min 22° for at least 15 min	Reported to be stable in 0 1 *N* HCl, as well as in the pH range 3–6 (ref 18)
Stable at pH 7 60° for at least 10 min 22° and 37° for at least 30 min	
Unstable at pH 8 6 37° for 30 min $n/n_0 = 0\ 03$	Unstable at pH 8 6, 37° Extrapolation of the data to 30 min $n/n_0 = 0\ 025$ (ref 19)
1 *M* NH_2OH, 22° $k^* = 0\ 25$ min^{-1} at pH 6 8 and 0 10 min^{-1} at pH 5 5	Reacts with 1 *M* NH_2OH at pH 7 to a greater degree than at pH 5 5 (ref 8)

* Assuming a first-order reaction, $dn/dt = -kn$, where n is the remaining activity at time t

Not all animal viruses can be inactivated with hydroxylamine under the conditions described here For example, Newcastle disease and mumps viruses, which are in one distinct sub-group of the myxoviruses[10], are resistant to 1 *M* hydroxylamine at 22° C Fowl plague virus and swine influenza virus, which belong to another sub-group[10], proved to be highly sensitive (Table 1) These results suggest that there are differences in the nucleic acids of these two groups of myxoviruses, although all myxoviruses which have been chemically analysed, including Newcastle disease[11], fowl plague[12], and influenza[13] viruses, contain ribonucleic acid Herpes simplex, which may contain deoxyribonucleic acid[14], also proved resistant to hydroxylamine The resistance of some viruses to hydroxylamine inactivation may be further evidence that hydroxylamine attacks a special configuration in the nucleic acid component of certain viruses, since it appears that all nucleic acids have certain chemical properties, such as a phosphate–sugar backbone, in common Thus it must be concluded that hydroxylamine does not alter any of the chemical bonds common to all nucleic acids

The biological significance of this hypothetical ester bonded to infectious ribonucleic acid is not clear One suggestion is that an amino acyl ester or some other acyl group in an ester linkage located at a terminal position on a ribonucleic acid chain would serve to limit the chain-length by providing the information that the end of the chain had been reached In any event, such a structure could serve to give the chain a direction in a more striking manner than that provided by the presence or absence of a terminal phosphate[15] Moreover, such a terminal ester group may serve as a priming agent for certain biosynthetic reactions

The theoretical and practical aspects of the phenomena described here are being investigated further and will be published in full detail elsewhere

AUXIN AND THE BULBING OF ONIONS

By Dr J E CLARK and Prof O V. S. HEATH
University of Reading Horticultural Research Laboratories, Shinfield Grange, Shinfield, Berkshire

DETAILED studies of those changes in the internal morphology and histology of onion plants which are characteristic of the process of bulb development in response to the combined stimuli of long days and high temperature led to the formulation of a speculative hypothesis in terms of a supposed 'bulbing substance' or hormone[1] We are now engaged in a study of the changes in growth-substance content of onion plants during bulbing, using modifications of the methods of paper partition chromatography combined with bioassay of growth-substances first developed by Bennet-Clark *et al* [2,3] , we are also studying the effects of externally applied auxin on bulb development

When testing for an unknown chemical growth-factor supposed to produce a specific effect on a certain organ of an intact plant it is desirable, if possible, to develop an assay method depending on the production under standard conditions of such an effect in the same or similar tissue Thus one should, ideally test a fractionated tissue extract for the presence of a 'flowering hormone' by its capacity to cause flower initiation in growing points, preferably kept under otherwise non-inductive conditions , the appropriate test for growth-promoting hormones is one in which increase of growth is measured, rather than inhibition of growth, or abscission of organs , for a bulbing substance' the assay method should involve bulb development, again preferably under non-inductive conditions If this principle is ignored, as is frequently the case, irrelevant or misleading information may be obtained For the comparison of amounts of known compounds in tissue extracts from plants in different treatments, the use of assay methods depending on irrelevant plant responses would, however, seem to be justifiable if suitable precautions are taken to confirm that the compound concerned is in fact the one supposed

For bioassay we have therefore used a modification of the wheat coleoptile cylinder test[4] in an attempt to compare changes in the 3-indolylacetic acid content of onion plants during bulbing in long days with that of plants remaining in short days, but we have also developed a method in which onion seedlings constitute the test material and show an increase in 'bulbing ratio' (the ratio of the greatest diameter to the least) when supplied with a suitable growth substance in darkness The onion seedlings as used for this bioassay have been found not only to give a marked bulbing response to long days but also to externally applied 3-indolylacetic acid in darkness Seedlings at the 2-leaf stage of development, with roots and leaf-blades removed ('seedling sections'), rotated horizontally in darkness in a 1 per cent sucrose solution, show from 1 to 8 days an increasing bulbing ratio in the presence of added 3-indolylacetic acid (sodium salt, *p*H 7 0, at 1×10^{-4} *M* concentration, or approximately 20 p p m), whereas in sucrose alone there are no marked or consistent changes Such a response is rapid at 25° C , much slower at 20° C and almost non-existent at 15° C , this resembles the effect of temperature on rate of bulbing in response to the stimulus of long days[5] We have also found, with intact seedlings growing in water culture in short days, a small but statistically significant ($P < 0\ 02$) increase in bulbing ratio due to the addition of 1×10^{-4} *M* 3-indolylacetic acid to the solution, as compared with seedlings not given 3-indolylacetic acid.

We have made a preliminary survey of the changes, caused by various periods in long days at different stages of development, in the growth-substance content of onion plants For this purpose plants of variety Ebenezer were grown from sets in sand culture in short days (less than 12 hr) and transferred to long days (17 hr) at the time of expansion of the tenth, fourteenth, eighteenth and twenty-fourth leaf Samples were taken from long-day and short-day plants of the same age according to the plan shown in Table 1 Roots and leaf blades were removed and an ethanol extract made of the remaining tissue The method of fractionation was that of Bennet-Clark *et al* [3] and Larsen[6], except that the *p*H was brought to 2 5 with 20 per cent orthophosphoric acid Only the ether-soluble, acidic fraction has so far been investigated in detail Extracts were chromato-

Table 1

Days from start of long-day treatment	No. of leaves emerged at start of long-day treatment: 10	14	18	24
0	*P* 1, 2 *E* 1 H_2O 1	*P* 1, 2	*P* 1, 2 *E* 1, 3 *B* 1	*P* 1, 2
3	*P* 1, 2 *E* 1 H_2O 1	*P* 1, 2	*P* 1, 2 *E* 1, 3 *B* 1	*P* 1, 2
5	*P* 1, 2 *E* 1	*P* 1, 2		*P* 1, 2
7	*P* 1, 2 *E* 1	*P* 1, 2	*P* 1, 2 *E* 1, 3 *B* 1	*P* 1, 2
10		*P* 1, 2		*P* 1, 2
14	*P* 1, 2 *E* 1	*P* 1, 2	*P* 1, 2 *E* 1, 3 *B* 1	*P* 1, 2
21		*P* 1, 2	*P* 1, 2 *E* 1, 3 *B* 1	*P* 1, 2
28		*P* 1, 2	*P* 1, 2 *E* 1, 3 *B* 1	*P* 1, 2

Key to solvents used: *P*, *iso*-propanol (80)/water (10)/(ammonia 10); *E*, ethanol (80)/water (10)/(ammonia 10); *B*, *n*-butanol (80)/water (10)/(ammonia 10); H_2O, water.
Key to assay used: 1, wheat coleoptile straight growth; 2, colorimetric determination; 3, onion seedling section ('bulbing')

graphed and assayed, in the way indicated in Table 1, after being kept for not more than 48 hr. in darkness and at + 2° C. All chromatograms were cut into tenths before being assayed. Marker spots of 3-indolylacetic acid, run in the presence of onion extract and sprayed with ferric chloride–perchloric acid reagent[2], indicated the position in which 3-indolylacetic acid would be expected to occur. Making use of this information, the 3-indolylacetic acid content of the extract was estimated, in every case, by a modified Salkowski determination[7], after elution from a chromatogram with absolute ethanol. The growth promotion produced in the coleoptile tests by the sections of the chromatograms where 3-indolylacetic acid was expected to run was compared as between long-day and short-day plants and was also compared with that produced by known amounts of 3-indolylacetic acid run at the same time; thus a second, very approximate, estimate of the amount in the onion tissue was available. These results yielded the following information.

In short days a growth substance which ran on chromatograms in all the solvents tried at approximately the same R_F as 3-indolylacetic acid (added to onion extract) was almost always found. As estimated colorimetrically this amounted to about 2.5 mgm. 3-indolylacetic acid per kgm. fresh weight at the tenth leaf stage and 3–4 mgm./kgm. at the later stages investigated. The coleoptile tests suggested a more marked trend from about 0.2 mgm./kgm. at the tenth leaf stage to about 1.0 mgm./kgm. at the eighteenth and twenty-fourth leaf stages.

Following transfer to long days there was in all stages a rapid increase in 3-indolylacetic acid to a maximum at 3–5 days followed by a fall to a value below that for the short-day controls. The initial rise was greatest for the twenty-fourth leaf stage (Fig. 1), in which the maximum reached the high value of about 9.6 mgm./kgm. This was enough to give the characteristic colour with ferric chloride–perchloric acid spray. The estimate based on the coleoptile test was about 7.0 mgm./kgm. for the maximum in the long-day plants and was about 1.0 mgm./kgm. in short days.

The onion seedling section assay showed increases in bulbing ratio in the zone in which 3-indolylacetic acid would be expected to run; these indicated changes in '3-indolylacetic acid' content similar to those shown by the coleoptile test, that is, a steady moderate amount in the short-day plants and in the long-day plants an increase to a maximum at 3 days, followed by a fall to below the value for the controls by 14 days. There were no indications of any other 'bulbing substances'.

The possibility must be considered that some 'bulbing substance' other than 3-indolylacetic acid ran in approximately the same position on the chromatograms; it would, however, be unlikely to have the same R_F as this in all four solvents used, to produce similar effects both in wheat coleoptile growth and bulbing of onion seedling sections, and to give the distinctive colour reactions observed with the ferric chloride–perchloric acid spray and in the modified Salkowski determination. It is conceivable that a compound which was not 3-indolylacetic acid and which changed in concentration during bulbing became converted into 3-indolylacetic acid during the extraction procedure or during separation on the chromatograms; the latter possibility is rather discounted by the consistent result obtained with water as the running solvent and for the present the substance will be assumed to be 3-indolylacetic acid. If correct this is one of the few cases yet cited of a morphogenetic effect being associated with a known growth hormone.

It is worthy of note that in all the stages the 3-indolylacetic acid in the long-day plants had fallen to a value below that in the short-day controls by 14 days from the date of transfer—approximately the time at which a measurable increase in bulbing ratio first occurred under the conditions in which these plants were grown. Thus it appears that the swelling of the leaf bases characteristic of bulbing[1] can only be due to high 3-indolylacetic acid content as an after-effect; it might even be thought to be brought about by a sub-normal 3-indolylacetic acid level, but

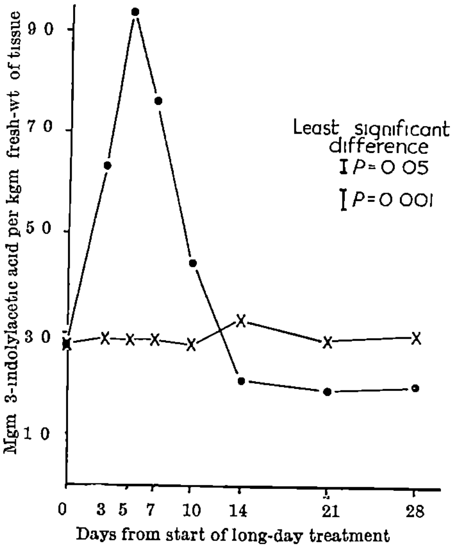

Fig. 1. Colorimetric determination of 3-indolylacetic acid content of plants at 24-leaf stage. ●—●, Long-day plants; ×—×, short-day controls

the onset and continuance of bulbing with a maintained external supply of 3-indolylacetic acid must be remembered here. The suppression of growth of the blades of the leaf initials, the first noticeable change in the internal morphology with the onset of bulbing[1], may be begun by the rise in 3-indolylacetic acid content, but it continues long after the subsequent fall. No account is here taken of possible differential distribution of the 3-indolylacetic acid and it is hoped to investigate this later.

This work is supported by the Agricultural Research Council, to which grateful acknowledgment is made, and much of it was carried out in the Research Institute of Plant Physiology of the Imperial College; it is being continued here and will be published in detail in due course. [March 12.

A NON-DIALYSABLE INHIBITOR OF GLUTAMO-TRANSFERASE PRESENT IN EXCISED TOMATO ROOTS

By C. S. VAIDYANATHAN and PROF. H. E. STREET
University College of Swansea

EXCISED tomato roots grown with either nitrate or ammonium as nitrogen sources accumulate the amides, glutamine and asparagine[1]. Attempts to study the mechanism of glutamine synthesis, by using homogenates of 21-day-old cultured roots, has led to the detection and partial purification of a natural non-dialysable inhibitor of the glutamo-transferase reaction.

Glutamine synthetase[2] promotes, at almost similar rates, the reaction of L-glutamate with either ammonia or hydroxylamine leading to the formation, respectively, of glutamine and γ-glutamylhydroxamate. Adenosine triphosphate and Mg^{++} (or Mn^{++}) are essential cofactors; maximal activity is obtained by the further addition of cysteine. Highly purified preparations of glutamine synthetase show[3], in presence of the metal activator, adenosine-diphosphate, and either phosphate or arsenate, glutamo-transferase activity:

$$\text{glutamine} + NH_2OH \rightarrow \gamma\text{-glutamylhydroxamic acid} + NH_3$$

It is possible, therefore, to use this reaction as an index of glutamine synthetase activity in crude preparations containing adenosine triphosphatase and to determine the hydroxamic acid formed by a colorimetric method[4].

A pea meal homogenate (5 gm. meal to 15 ml. water), partially clarified by centrifuging at 2,000 r.p.m. for 15 min., was used as the source of glutamo-transferase in the exploratory experiments first described. The standard reaction mixture (2.5 ml.) for assay of glutamo-transferase activity contained: 0.5 ml. 0.1 *M* *tris* buffer (*p*H 7.2), and 0.1 ml. of each of the following: manganese sulphate (0.01 *M*), sodium arsenate (0.1 *M*), sodium-adenosine triphosphate (0.001 *M*), L-glutamine (0.1 *M*), hydroxylamine (0.1 *M*, adjusted with sodium hydroxide to *p*H 7.2). The standard reaction time was 3 hr. at 35° C. Under these conditions the pea meal preparation produced, on different occasions, 3.6–4.8 μmoles glutamylhydroxamate.

Clones of excised tomato roots (*Lycopersicum esculentum*, Mill. var. Sutton's Best-of-All) were cultured in penicillin culture flasks containing 1 l. of a modified Whites's medium[5]. Twenty 10-mm. root tips, from sector cultures, were introduced into each culture flask and growth allowed to proceed for 21 days at 27° C. Root homogenates (1 gm. fresh wt. roots to 3 ml. water), prepared from different clones, uniformly lacked glutamo-transferase activity but differed in the extent to which they inhibited the transferase of the pea meal preparation when 0.5 ml. aliquots were incorporated in the standard reaction mixture. Homogenates from 15-day-old seedling roots of the same variety of tomato had low inhibitory activity and the inhibitory activity of the excised root clones rose to a steady value during the early subcultures following initiation.

The nitrogen source of standard Whites's medium is nitrate (45 mgm. nitrogen/l.) and its *p*H is 4.6. Homogenates of roots grown, respectively, with nitrite[6] (7.0 mgm. nitrogen/l. at *p*H 6.0), ammonium[6] (4.5 mgm. nitrogen/l. at *p*H 6.8), or L-glutamine (4.8 mgm. nitrogen/l. at *p*H 6.8) as nitrogen sources were also tested for their inhibitory activity, the homogenates being prepared at a strength (1 gm. fresh wt. roots to 5 ml. water) such that 0.5 ml. homogenate from the nitrate-grown roots of the clone produced about 50 per cent inhibition (Table 1).

Table 1. INFLUENCE OF NITROGEN SOURCE ON THE INHIBITORY ACTIVITY OF ROOT HOMOGENATES

Nitrogen source for root growth	Glutamylhydroxamate (μmoles)
No homogenate added	4.50
Nitrate	2.34
Nitrite	2.70
Ammonium	2.07
L-Glutamine	0.68

Two excised tomato root clones (clones 1 and 2) were used in further study of the inhibitor. Its solubility differed in the two clones. When the homogenate of clone 1 was centrifuged, the clear supernatant had very low activity and the inhibitor was liberated from the tissue residue by treatment with 0.1 *M* arsenate for 1 hr. (by repeated extraction in this way most of the activity could be removed from the residue). Clone 2, by contrast, yielded a supernatant of high activity, and little further activity was extracted from the residue by a single arsenate treatment (Table 2).

Using the total homogenate of clone 1 roots it was shown that, when added to the reaction mixture after 3 hr. incubation, it stopped the transferase reaction, but during 5 hr. further incubation did not decrease the hydroxamic acid content. The soluble inhibitory

Table 2. DISTRIBUTION OF INHIBITORY ACTIVITY IN ROOT HOMOGENATES

Addition (0·5 ml.) to reaction mixture	Glutamylhydroxamate (μmoles) Clone 1	Clone 2
Water	4·26	3·75
Supernatant	3·83	0·84
Arsenate extract of residue	0	3·58
Tissue residue	0	0
Residue after ten extractions with arsenate solution	3·94	

activity of the primary supernatant (clone 2) or of the arsenate extract (clone 1) was thermolabile (Table 3). These solutions did not decrease in activity when dialysed against distilled water for 48 hr. and were free from detectable proteolytic and adenosine triphosphatase activity.

Table 3. THERMOLABILITY OF THE SOLUBLE GLUTAMO-TRANSFERASE INHIBITOR OF CLONE 2 ROOTS

Time (min.) of exposure of inhibitor solution to 100° C.	Glutamylhydroxamate (μmoles)
0	0
5	0·8
10	1·2
15	2·5
30	3·7
45	4·5
60	4·5
Water control	4·65

A purified preparation of the glutamo-transferase enzyme was at this point obtained from 2 kgm. dried pea meal (*Pisum sativum* var. Meteor) by the method of Elliott[7], dissolved in the *tris* buffer, and the sensitivity of both the transferase and the synthetase activities of the enzyme to the tomato root inhibitor tested. The standard reaction mixture (3·3 ml.) used in assaying glutamine synthetase activity contained 0·5 ml. 0·1 M *tris* buffer (pH 7·2), 1 ml. enzyme solution, 0·5 ml. sodium-adenosine triphosphate (0·05 M), 0·5 ml. sodium glutamate (0·5 M), 0·1 ml. manganese sulphate (M), 0·1 ml. hydroxylamine (M and adjusted to pH 7·2), and 0·1 ml. cysteine (M). In these tests a partially purified preparation of the inhibitor was used. This was prepared from a clone 2 root homogenate (100 gm. fresh wt. roots to 200 ml. water) as follows: the supernatant was treated with 300 ml. acetone and the precipitate collected by centrifuging, washed with acetone and reduced to a dry powder in a vacuum desiccator. Half the acetone powder dissolved in 50 ml. water was treated with an equal volume of saturated ammonium sulphate solution and the precipitate collected by centrifuging and dissolved in water. This solution was dialysed at 2–5° C. for 48 hr. and then adjusted to 50 ml. The preparation of an active acetone powder ensured inactivation of any glutaminase[8] or adenosine triphosphatase[9] contamination. The inhibition, by the purified inhibitor, of the transferase activity of the pea meal enzyme is shown in Table 4.

Inhibition of the transferase activity by the purified inhibitor was not reduced by addition of 0·05 M cysteine or glutathione. Its inhibitory activity was maximal if incubated with the pea enzyme for 10 min. before adding substrates and cofactors. Prolongation of this preincubation for 60 min., using an inhibitor addition causing about 50 per cent inhibition, did not lead to any further decrease in enzyme activity. The inhibition was only slightly reduced by increasing the concentrations of glutamine or adenosine triphosphate in the reaction mixture (Table 5). There was no evidence that the inhibitor reduced the effective concentrations of Mn^{++}, arsenate or hydroxylamine.

Table 4. ATTEMPTED PURIFICATION OF THE GLUTAMO-TRANSFERASE INHIBITOR PRESENT IN EXCISED TOMATO ROOTS

Inhibitor fraction	Dry wt. inhibitor required to cause 50 per cent inhibition of transferase activity (μgm.)
1. Original supernatant	1,200
2. Acetone powder	450
3. Dialysed ammonium sulphate precipitate	76

Table 5. EFFECTS OF L-GLUTAMINE AND ADENOSINE TRIPHOSPHATE CONCENTRATIONS UPON THE PERCENTAGE INHIBITION OF GLUTAMO-TRANSFERASE ACTIVITY BY THE PARTIALLY PURIFIED TOMATO ROOT INHIBITOR

	Glutamylhydroxamate formed (μmoles)		
L-Glutamine (mM)	Inhibitor omitted	Inhibitor present	Percentage inhibition
4	2·4	1·14	53
8	4·0	2·2	45
12	5·7	3·4	41
20	8·1	4·95	39
ATP(M)			
10^{-5}	0·6	0·24	60
4×10^{-5}	2·1	0·90	57
10^{-4}	3·4	1·5	55
4×10^{-4}	3·8	1·9	50
10^{-3}	3·6	1·9	47

The inhibitor was active against both the transferase and the synthetase activity of the pea meal enzyme (Table 6).

Table 6. ACTIVITY OF THE PARTIALLY PURIFIED INHIBITOR AGAINST THE TRANSFERASE AND SYNTHETASE ACTIVITIES OF THE PEA MEAL ENZYME

	Glutamylhydroxamate formed (μmoles)		
Enzyme activity	Inhibitor omitted	Inhibitor present	Percentage inhibition
Glutamo-transferase	4·70	1·03	78
Glutamine synthetase	6·31	2·77	56

Homogenates of seedling roots of pea (*Pisum sativum* var. Meteor) also showed inhibitory activity, but it could not be detected in red clover roots (*Trifolium pratense* var. Dorset Marlgrass), and seedling roots of *Avena* (var. Victory) showed high glutamo-transferase activity.

Acknowledgment is made to the University College of Swansea for a research fellowship and to the Indian Institute of Science for the leave of absence which enabled one of us (C. S. V.) to undertake this work, to Prof. H. Waelsch of Columbia University for a pure sample of glutamylhydroxamic acid and to Imperial Chemical Industries, Ltd., for a grant towards the purchase of the Unicam spectrophotometer (*SP* 500) used in the estimation of the hydroxamic acid.

FORTHCOMING EVENTS

Monday, September 21

Institute of Metal Finishing (at the Northampton Polytechnic, St John Street, London, E C 1), at 6 15 p m —Mr A O F Freund and Mr A H Barber "The Use of Titanium in Electrolytic Processes for Metal Finishing"

Thursday, September 24

Oil and Colour Chemists' Association (at Manson House, 26 Portland Place, London, W 1), at 7 p m —Mr J A L Hawkey "A Technologist's View of 'The Fourth Epoch' "

Friday, September 25

Hospital Physicists' Association (in the Lecture Theatre, Main Medical School, King's College Hospital, Denmark Hill, London, S E 5), at 8 30 p m —Prof D G Catcheside, F R S "The Influence of Nutrition on Mutation Induced by Radiation" (Sixth Douglas Lea Memorial Lecture)

Wednesday, September 30

British Institution of Radio Engineers (at the London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, London, W C 1), at 6 30 p m —Mr W E Willshaw "Modern Microwave Valves—a Survey of Evolution, Principles of Operation and Basic Characteristics"

Thursday, October 1—Friday, October 2

Institute of Biology (in the Lecture Hall, Royal Geographical Society, Kensington Gore, London, S W 7), at 10 a m daily—Symposium on "Biological Problems Arising from the Control of Pests and Diseases"

Society of Chemical Industry, Food Group (at the Royal Society of Medicine, 1 Wimpole Street, London, W 1)—Symposium on "Enzymes in the Manufacture, Storage and Distribution of Food"

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned

Research Assistant (preferably graduate in mathematics and experience in the use of digital computers) in the Computing Laboratory, to assemble and run programmes using the Interpretative Schemes in the Deuce Computer—The Secretary of University Court, The University, Glasgow (September 28)

Assistant Lecturer in Botany—The Registrar, The University, Manchester 13 (September 30)

Technical Assistant (qualified to maintain and supervise the use of X-ray apparatus and the electron microscope) in the Houldsworth School of Applied Science—The Registrar, The University, Leeds (September 30)

Lecturer in Philosophy—The Secretary, The University, 38 North Bailey, Durham (October 1)

Lecturer in the History of Science—The Registrar, The University, Leicester (October 1)

Research Assistant (graduate) in the Department of Agriculture, to carry out investigations into the efficiency of farm buildings by the application of work study methods—The Secretary and Registrar, University College of North Wales, Bangor, North Wales (October 1)

Lecturer or Senior Lecturer in Physics and/or Chemistry, to take subject to Pass Degree standard—The Principal, Bede College, Durham (October 3)

Reader or Senior Lecturer (with experience in experimental physics, and preferably experience in some aspects of applied physics) in the Department of Physics of the Faculty of Science—The Registrar, The University, Manchester 13 (October 5)

Lecturer (with special qualifications in hydrography) in Geography—The Registrar (Room 22, O R B), The University, Reading (October 10)

Chair of Physics, Chair of Chemistry, and Chair of Biology in the Royal University of Malta—The Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W C 1 (October 15)

Lecturer or Assistant Lecturer in Bacteriology at the University of Malaya (Singapore Division)—The Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W C 1 (October 15)

Lecturer (with a qualification in biochemistry and preferably with a medical qualification) in Chemical Pathology—The Dean, St Thomas's Hospital Medical School, London, S E 1 (October 15)

Lecturer or Assistant Lecturer in Physics at Makerere College (University College of East Africa)—The Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W C 1 (October 20)

Lecturer in Microbiology in the Faculty of Rural Science, University of New England, Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W C 1 (Australia, October 23)

Lecturer in Nutrition in the Faculty of Rural Science, University of New England, Australia, to undertake teaching and research in livestock nutrition in the Department of Nutrition and Chemical Pathology—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W C 1 (Australia, October 23)

Lecturer, Senior Lecturer or Associate Professor in Applied Genetics at the University of New England, Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W C 1 (Australia, October 23)

Senior Lecturer (preferably with research experience in the field of neurohistology) in Physiology at the University of Sydney, Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W C 1 (Australia, October 24)

Chair of Botany—The Secretary, The Queen's University, Belfast (October 31)

Chair of Inorganic and Physical Chemistry in the University of Tasmania—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W C 1 (Australia, October 31)

Demonstrators in Biochemistry, Animal or Plant Physiology, Soils, Parasitology, Livestock Anatomy and Histology, Nutrition, Agronomy, Livestock Husbandry, and Physiology— The Registrar, University of New England, Armidale, N S W , Australia (October 31)

Senior Research Fellow or Research Fellow in the Department of Theoretical Physics, Research School of Physical Sciences, Australian National University—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W C 1 (Australia, November 2)

Lecturer (with qualifications in either pure or applied mathematics) in Mathematics at the University of Canterbury, Christchurch, New Zealand—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W C 1 (New Zealand, November 30)

Assistant or Associate Professor of Pathology at Queen's University, Kingston, Canada—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W C 1

Lecturer in Mathematics—The Secretary, Royal College of Science and Technology, Glasgow

Research Assistants (graduates) in Electrical Engineering, for work in the fields of transistor applications or the properties of dielectric materials—Head of the Electrical Engineering Department, Northampton College of Advanced Technology, St John Street, London, E C 1

Research Assistants (2) in Physics, one for theoretical and/or experimental work connected with the theory of liquids, and the other for meteorological or solid state physics—The Secretary, Sir John Cass College, Jewry Street, London, E C 2

Senior Technical Officer (with a degree or diploma in agriculture or agricultural botany) in the Cereals Section of the Seed Production Branch—The Secretary, National Institute of Agricultural Botany, Huntingdon Road, Cambridge

NUCLEAR POWER AND ITS DEVELOPMENT

SIR JOHN COCKCROFT is reported to have expressed the opinion on April 26 that in 1966 some 25 per cent of the requirements of the United Kingdom for electricity would be met by nuclear generation, 50 per cent by 1975 and 100 per cent by the end of the century. Questions asked in the House of Commons on June 8 indicate a disposition to allow political and social considerations to over-ride, if not distort, the technical and economic aspects, and there have been other attempts to make the effect on the coal industry the deciding factor in determining the development of nuclear power. The implications of technological change have been ignored, as has the effect of development on the cost of electricity supplied by nuclear power-stations, which Sir Christopher Hinton stressed very strongly in his Axel Axson Johnson Lecture delivered at Stockholm on March 15, 1957.

In his reply on behalf of the Government, the Paymaster-General was emphatic that the programme for the development of nuclear energy in Britain over the next few years was arranged after careful consideration, and it certainly could not be upset on any temporary considerations. An admirable broadsheet, "Prospects for Nuclear Power" (No. 431, March 1959), issued by Political and Economic Planning, is well designed to remove misunderstandings and facilitate an objective approach to this problem, in which it is extremely difficult to separate at all sharply the technical and economic from the political and social elements. Although the broadsheet is particularly concerned with the world position and Britain's export prospects, it includes a lucid discussion of the impact of nuclear power which deserves to be widely read. The brief paragraph on the position in the United Kingdom points out that by 1966, when the dozen or so nuclear power-stations required to supply the target capacity of 5,000–6,000 MW. are in operation, the cost of the electricity generated should be almost competitive with that from other types of power-stations wherever sited; this answers the criticism implied in the questions in the House of Commons.

The broadsheet points out that by 1966 the nuclear power-stations will be supplying a quarter of the electricity used in Britain and doing the work of 18 million tons of coal a year, and that it is estimated that the cost of generating electricity from the largest of the stations now under construction, that at Hinkley Point, will be between 0·59*d*. and 0·66*d*. per kWh., compared with 0·53–0·64*d*. for an up-to-date coal-fired plant. The cost of electricity from the largest station now being built is competitive with that from a high-efficiency coal-fired station built on the same site. Moreover, for the later stages of the present programme, when all new generating plant may be nuclear, Britain is considering types of reactor that will be cheaper to build and more efficient to operate, as well as able to accept re-cycled plutonium to replenish the burnt fuels, and these types should produce electricity more cheaply than conventional plants. Two such reactors are the gas-cooled heavy-water moderated reactor, and the advanced gas-cooled reactor: an experimental version of the latter is already being built at Windscale.

These facts, which were essentially given by Sir Ian Horobin in moving the second reading of the Electricity (Borrowing Powers) Bill on January 20, sufficiently display the tendentious character of the question to which Sir Ian replied in Parliament on June 8. It should also be remembered that the high-temperature gas-cooled reactor is to be studied at Winfrith Heath, and the sodium-cooled fast-breeder reactor at Dounreay, both with the subsequent period in mind when reactors will be needed to take over an increasing proportion of the base load. From the Dounreay reactor, to be in operation this year, will come the data necessary to enable fast reactors using plutonium fuel to be integrated with existing thermal reactors. This will improve the burn-up of natural uranium to somewhere near the theoretical limit. The reactor programme is also supported by large facilities for research and an extensive research programme, while production and fuel-processing facilities are also well developed in Britain, and capacities are sufficient to meet the needs of other countries. Lord Mills, the Minister of Power, stated explicitly in the House of Lords on March 3 that the nuclear-power programme for 1964 onwards had not yet been determined.

This position, however, needs to be set against the general background outlined in the PEP broadsheet, which stresses, too, the dynamic nature of the energy position, both nationally and internationally, and the way in which non-economic influences often determine the most economical way of meeting demands for energy. The great promise of nuclear energy is that, with ample resources of uranium and thorium, and the high energy content of each ton of raw material which makes transport a negligible factor, it will eventually provide all nations with an unlimited and virtually indigenous supply of energy at an economic cost. Although this lies well into the future, nuclear energy should make an immediate though modest contribution, particularly in Europe.

The factors which limit this contribution must be carefully noted in an objective assessment of the situation. First, for technical reasons, nuclear fission reactors are only efficient when employed in large units. The large amounts of electricity produced from each nuclear power-station can in the near future be generated at an economic cost only if they can be used to the maximum. This is only possible where electricity systems are fully developed in a grid-network such as an industrial area provides

Accordingly, nuclear energy is as yet unlikely to help under-developed countries, nor will it be suitable for some time for the direct production of heat where small units are normal In Europe, where fossil fuels are expensive, nuclear energy should be competitive within the next ten years for what is called base-load operation, that is, power-stations operating virtually all around the clock feeding electricity into the grid

The second factor is that small coal is particularly suitable for power-stations, and the proportion of small-coal production is continually growing as more coal is mined by mechanical methods This coal can only be burnt efficiently in very large plants and its use is thus almost confined to power-stations Criticism of Britain's nuclear-power programme arises largely from this fact that nuclear energy is suitable for the production of electricity only in the conditions to which the growing quantity of small coal is also suited

The third factor is that production of electricity at a price competitive with conventional power only means an additional supply of electricity and not the introduction of a cheap new fuel Electricity has its own particular advantages, and its use in Britain is continually growing , but it is not, at present costs, an economic substitute for other sources of energy for many purposes The nuclear-power programme should enable those needs to be met more easily, but it will not obviate the need for other fuels for these purposes Nevertheless, the development of nuclear energy holds great promise, and Britain's prompt start has given her an early lead in tackling the vast technical problems involved, and only the U S S R and the United States have programmes at all comparable in size to the British Moreover, the British power programme, based on the gas-cooled natural-uranium reactor, is the only large-scale programme which is being carried out in a Western country, and the British type of reactor has been proved in operation, having supplied electricity to the grid for some two years

Nevertheless, the survey in *Planning* of the prospects for British exports of nuclear power-stations and related fuel and equipment leads to the conclusions that the prospects for British firms to export reactors are not so bright as they were once thought to be Nuclear power is indeed regarded as the most helpful long-term solution of the fuel problem in many European countries, and the principal countries are in a position to exploit nuclear power without too much difficulty They possess the necessary scientific and technical skills and the capacity to build equipment, and they will therefore want to develop their own nuclear industry as fast as they can They may buy one or two reactors from other countries, as Italy has done, in order to gain experience of operation and construction ; but after that they will probably do more and more of the work themselves They are unlikely to set up their own fuel-processing plant, partly because of expense and partly because most European countries have no uranium deposits and are unlikely to obtain uranium without some control against the production of plutonium France is the one country of Europe which will have a self-contained nuclear industry

In the Scandinavian countries, and possibly in Spain and Portugal, competition is likely to be fierce, and although the Calder Hall power-station has impressed potential customers with the merits of the British type of reactor, steady and impressive publicity is required Outside Europe, the first markets —for the next ten years at least—will be in Japan and India, but China is likely to be tied to Russian developments at first Several countries in Latin America might prove customers for the British type of large power-station reactor

Whether British or American power reactors are bought—and these are the only countries at present offering to sell power reactors and supporting the offer with a fuel service—the PEP broadsheet suggests that the future of the nuclear reactor export market is closely tied to a successful small reactor A cheap small reactor similar to that for moderately powered gas-turbine and diesel-powered generating sets could transform areas which are now under-developed Here, since British efforts have been concentrated on the Calder Hall type, Britain is less favourably placed than the United States to design reactors for special conditions Without the urgency of Britain's fuel problems, the United States has been able to experiment with a wide variety of types of reactor, and this could prove an important advantage in meeting the future export demand for a small and flexible reactor system Besides this, the United States is at present the only country that can supply enriched uranium for reactors abroad

Britain is now taking the preliminary steps to enable her to meet the demand for small reactors, but it is possible that the Soviet Union, although it has not yet been active in export competition, could also have an advantage over Britain in the matter of reactor types Nevertheless, the broadsheet points out, reactors are not the only product that can be exported The one part of the British power-reactor which is not manufactured by industry is the fuel element The rest, including ancillary equipment, such as turbines, generators, handling gear, processing equipment and control instruments, are all the products of industrial firms Lord Mills, it is true, has directed attention to the more limited opportunities in the near future for new consortia of firms with design teams trained by the Atomic Energy Authority and which would be capable of tendering for the construction of complete nuclear power-stations , but at the same time, he emphasized the opportunities for the manufacture of small reactors, including research reactors.

Nuclear energy, as the PEP broadsheet puts it, means that there will be an increased demand for those products which British firms can supply as cheaply as any of their competitors , but the prospects for British exports of nuclear reactors and equipment are not determined solely by the competitive ability of British firms One dominant factor will be the political agreements that the Government is able to make. Marketing nuclear reactors is not purely a commercial undertaking, for, as the broadsheet duly notes, international politics are involved, and unless this is clearly understood British chances of building up an export trade will be small.

For this reason alone, it is important that Britain should establish close and satisfactory relations both with the International Atomic Energy Agency and the European Organization for Nuclear Research, and also with Euratom—the European Atomic Energy Community and its six members. A second factor, however, to which *Planning* does not direct attention is that of scientific and technical man-power. Although in the stricter sense this lies outside the scope of the broadsheet, it is probably the ultimate factor on which the prospects for British development of nuclear energy depend. Unless the resources of scientific and technical man-power in Britain are fully developed and effectively used, Britain is unlikely to be able to seize the opportunities that nuclear energy will bring—even to secure all the advantages which its development in Britain might offer to the economy of the country—still less to hold her own in the keen competition forecast in this broadsheet. Nor is this simply a matter of training sufficient scientists and technologists: it is also a matter of seeing that they are wisely used, that our organization and administration of research are adequate and in balance, and that the administrators and statesmen called upon to handle the complex and interlocked technical, economic and social problems which the development of nuclear power will bring are competent to give due weight to all the scientific and technical issues, no less than to the economic or political aspects of the situation.

For some months Euratom experts have been drafting a new and realistic programme for the six member countries, taking account of changing oil and coal prices. Since the PEP broadsheet was issued, the report on this programme has been finished, but owing to disagreement at the top it has been withdrawn and is not to be published. This disagreement has jettisoned Euratom's plans for all but the 1,000-megawatt programme being carried out with American aid, and it is obvious from the broadsheet that most of the chances open to British industry of tendering for foreign nuclear power-stations have likewise disappeared.

Sir Ian Horobin took a far more confident view in replying in an adjournment debate on the nuclear power programme in Britain in the House of Commons on July 1. He confirmed that latest figures gave the cost of electricity from conventional stations as 0·5–0·65*d*. a unit compared with 0·65–0·7*d*. for electricity from nuclear power-stations; but he emphasized that the statement that nuclear energy to-day is 40 per cent more expensive than conventional power was based on a comparison of the cheapest possible coal and the dearest existing nuclear energy. Sir Ian suggested that the real difference is probably more like 15–20 per cent, and he pointed out that in view of the 70 per cent rise in the price of coal over the past ten years it would have been unrealistic to base policy on the assumption that coal would not be 5–7*s*. a ton dearer than it is now. He also thought that the price of uranium will fall when the present contracts expire and that this factor, with a further slight rise in the price of coal, is likely to decrease the margin of 15–17 per cent against nuclear energy, and that the price of generating electricity by nuclear energy is likely to touch that of generating by coal in the late 'sixties.

Sir Ian Horobin insisted that the British nuclear-power programme is a very carefully considered whole, and that it is probable that what may be called the Calder Hall type of reactor has several years of valuable development before it. About 1961 the advanced gas-cooled reactor should become critical, and if this is successful the first commercial type may be in operation about 1965. The work done with the fast breeder reactor now being developed at Dounreay has been very successful and a period of low-power testing at Dounreay is expected to begin this summer. If all goes well, we may hope to have this type in operation by about 1970, and its low capital cost and its place in the balanced programme offer exciting possibilities, particularly in flexibility. By that time a substantial number of stations of the Calder Hall type would be in operation, all producing plutonium. We must bear in mind, Sir Ian said, the possibility of a situation arising when it would be possible to build very much larger stations than originally conceived and that perhaps only about half a dozen more stations would come into the programme. He repeated that we cannot afford to run any risk of completely unbalancing the structure of the industry in Britain by interfering with the present programme. When that programme is complete, further decisions will be required, and although preliminary consideration is being given by the Government to the subject, it is not thought that it is necessary to decide for a further year or two what stations should be built after 1965. It is very important, he said, that everyone should realize that a nuclear-power programme on the scale of that in Great Britain must be a long-term, carefully balanced programme and that it cannot be interrupted in response to short-term considerations. Britain is now the major civil nuclear Power, and the need for thought and care in investment and design are correspondingly great.

DARWIN WITHOUT MODERN SCIENCE

Darwin and the Darwinian Revolution

By Dr. Gertrude Himmelfarb. Pp. ix+422. (London: Chatto and Windus, Ltd., 1959.) 42*s*. net.

An adequate study of Darwin, his scientific achievements, and the result of his work in all the fields of human endeavour which they have affected makes rigorous demands on the competence of whoever attempts to write such a book. Dr. Himmelfarb brings to her task a concentration of interest and of effort, the former of which is passed on to the reader by the sustained vigour and elegance of her style and the skill with which the book is constructed, while the mastery of her technique hides the laboriousness of the work involved.

She has read practically everything there is to read by Darwin and on Darwin, including manuscripts hitherto unpublished, and has subjected the material to lucid analysis in terms of the history of Darwin's life, experiences, contacts with other persons, researches, results, doubts and beliefs. He is situated in his intellectual environment, his home life, his ailments real or imagined, and his place in history. The social, scientific, religious, political and general public climates of his day are vividly portrayed, and there can seldom have been a work of biography undertaken with such bibliographical care.

But while it would be difficult to exaggerate the excellence of this book as a contribution to the history of the events, ideas and arguments as a result of which Darwin produced his theory of evolution by natural selection, the case is altered when it comes to the evaluation of this theory in terms of the present state of scientific knowledge, because Dr. Himmelfarb's work is imbued with a relentless aversion to natural selection, pursued by means of a skilful and acute dialectic without reference or regard to the results of scientific research during the past fifty years. Indeed, this is directly implied by the statement (p. 366) that "the present status of Darwinism has not altered much since 1860, when Huxley pronounced it to be not an established theory but a tentative hypothesis". When she tries (p. 368) to substantiate such a view to-day by quoting William Bateson, she gives herself away at once.

That the author is not familiar with, or prefers to ignore, the growing edge of scientific knowledge by observation and experiment during the past fifty years appears from statements such as the following (p. 269): "In the experiments of Mendel and de Vries, new species appeared suddenly in the form of mutations". Mendel neither claimed nor obtained any such results. On the contrary, his genius lay in selecting for his experimental material strains which differed only in one or two characters: differences immeasurably inferior to those of specific rank. As for de Vries's 'mutations', it has long been recognized, thanks primarily to the work of T. H. Morgan and his colleagues A. H. Sturtevant, C. Bridges and H. J. Muller, that they are not mutations at all, but the results of a rare method of 'sporting' by permanently heterozygous strains technically known as the 'crossing-over of balanced lethals'.

When the author attributes to neo-Darwinians the statement (p. 270) that "only the smallest mutations could be favourable and that such favourable mutations were in fact so rare a phenomenon that without natural selection not even a fruit-fly, let alone a man, could have developed", and concludes, "Thus it became the very paucity of variations, the very improbability of their concurrence, that was now made to tell in favour of natural selection", she makes the elementary and very outdated mistake of thinking that mutation is the only supply of variation. It has long been known that recombination of genes is enormously greater as a source of supply of variation than mutation itself, and it produces gradual change.

Dr. Himmelfarb has not grasped the fundamental significance of the work of Sir Ronald Fisher, whom she calls "the mathematician". He showed, first, that natural selection of genes within the gene-complex is a universal phenomenon, which explains why the genes gradually *become* either dominant or recessive. This is how evolution proceeds. Mendelian genetics itself provides evidence of Darwinian selection. He showed, secondly, that selection is so much more powerful than mutation, that no mutation can have the remotest chance of becoming a normal component of a population if there is the slightest degree of adverse selection exerted against it. He showed, thirdly, that as all organisms are tolerably well adapted to the conditions under which they live in their present environment, the vast majority of mutations are bound to be deleterious to the organisms in the conditions under which they arise, and this proves that any attempt to explain evolution by an appeal to causes which might be supposed to impart favourable qualities or directions to mutations through 'inner feelings', '*élan vital*', 'urges', or the transmission of somatic modifications, is killed stone dead at the start. "Every theory of evolution which assumes, as do all the theories alternative to natural selection, that evolutionary changes can be explained by some hypothetical agency capable of controlling the nature of mutations which occur, is involving a cause which demonstrably would not work even if it were known to exist." The fact that wild species in Nature are highly heterozygous shows that mutant genes, subjected to adverse selection when they first arose, remain as recessives in the gene-pool, and function as a reserve which is drawn on when environmental conditions change, and some of these genes then become dominant by selection in the gene-complex, and established in the population. It can also be shown that selection is exerted in favour of the heterozygous state *per se*.

Results such as these should find a place in any modern appraisal of the position of natural selection at the present stage of knowledge; but Dr. Himmelfarb has preferred to say (p. 276) that "Posing as a massive deduction from the evidence, it (natural selection) ends up as an ingenious argument from ignorance". The word "ignorance" is a double-edged weapon when it is used by an author without any indication of awareness of the experimental results obtained by such distinguished scientists as E. B. Ford, C. D. Darlington, P. M. Sheppard, A. J. Cain, W. H. Dowdeswell, H. B. D. Kettlewell or C. H. Waddington, to mention only those working in Great Britain.

The intercalation of quotations from Darwin, labouring in his unavoidable ignorance of the principles of Mendelian genetics, to disparage arguments which have since been substantiated by the results of modern experimentation in natural selection is regrettable. When Darwin wrote a hundred years ago that "we are far too ignorant, in almost every case, to be enabled to assert that any part or organ is so unimportant for the welfare of a species that modification in its structure could not have been slowly accumulated by natural selection", he was quite correct, and it was merely tendentious for Dr. Himmelfarb to say (p. 276) that "three negatives do not normally constitute a positive". When Darwin went on to say that "it would be extremely bold to maintain that no serviceable transitions are possible by which these (electric) organs might have been gradually developed", he was prophetic, as Dr. Lissman's researches have since proved. The initial stages in the evolution of flight in birds, colour-vision, or the whale's adaptation for avoiding caisson-disease, to mention only a few additional striking cases, have all been shown to be capable of conferring survival value from the inception of the improvement

The statement (p 277) that "The eye is obviously of no use at all except in its final, complete form" completely ignores the comparative anatomy, embryology and physiology of the lower chordates, which show how light-sensitive cells in the epidermis have been brought into place, from the surface of the skin into the neural tube and then into the retinal layer of the eye-cup, and are functional at each stage Dr Himmelfarb (p 279) accuses Darwin of invoking the *perfection* of the eye at the same time as he quoted Helmholtz on the inadequacy and imperfection of the eye, but in the "Origin of Species" (World's Classics edition, p 190), Darwin wrote, "its marvellous yet not absolutely perfect characters" What Darwin claimed was that natural selection confers *improvement*, and in the case of the vertebrate eye this is undeniable to anybody familiar with the visual organs in *Amphioxus*

The statement that "the persistence without change of any forms over a long period of time is difficult to explain by natural selection" is particularly unfortunate, because so long ago as 1878 T H Huxley pointed out that natural selection is the only mechanism that can account both for change and for stability, and as recently as 1952 E B Ford supplied the genetic explanation of this by showing that the non-contamination of genes and the rarity of mutation produced stability, while the power of recombination of genes can produce endless variability, under the control of natural selection in each case

"How can selection, knowing nothing of the end or final process, function when the only test is precisely that end or purpose?" asks Dr Himmelfarb (p 277) The experimental results of investigations on the evolution of industrial melanism in moths show how the selective taking by predators of prey ill-adapted to their environment can be seen going on, and the intensity of the selection pressure can be measured with mathematical precision, mimetic resemblances in butterflies are improved and confer survival value in mathematical relation to the prevalence of distasteful models, the method of capture, marking, release and recapture enables the predations by thrushes on snails of different colours to be correlated with the seasonal variation of vegetation, and the longevity of different genetic types of moths to be measured in terms of concrete units of time That is how selection actually operates

Astonishingly out of date is the statement (p 284) that "the entire discussion of sexual selection is anthropomorphic in its basic conception, for whether the coloration of a bird is judged to be either beautiful or monstrous, it is by human standards that the judgment is made" It is now quite clear that the 'beautiful' *and* 'monstrous' colours in question, to which must be added structures, attitudes, and behaviour-patterns used in courtship, function, as Sir Julian Huxley, N Tinbergen and many others have proved, as stimuli by which a threshold physiological condition in the partner is reached and a release mechanism set in motion There is no question of any anthropomorphic æsthetic choice

It is quite correct that many of the examples which Darwin thought conformed to the principle of sexual selection have since been found to owe their origin to other than epigamic causes, such as warning marks, recognitional or threatening defensive characters But some characters, as those of the male peacock, ruff, or argus pheasant, are good examples of the sexual selection in Darwin's sense, as Sir Julian Huxley showed more than twenty years ago, yet Dr Himmelfarb concludes (p 300) that "Sexual selection has all the faults of natural selection and more: the suspicious facility with which it can be made to explain anything and everything, the manipulation of evidence for whatever purposes are convenient, and the invocation of ignorance when all else fails" Here, again, the historical present tense is used, but there is nothing to show that the author does not intend it to apply to the present and that the remarks made represent the actual state of scientific knowledge

Turning now to another discipline of science, we find Dr Himmelfarb stating (p 271) that, "Geology, however, has been notably unforthcoming, and instead of being the chief support of Darwin's theory, it is one of its most serious weaknesses" It is difficult to believe that such a phrase could have been written in 1959 for 1959 She goes on to say that "It might have been expected that in those cases where the geological record is more or less complete we would find closely graduated varieties of species existing at the beginning and at the close of the period Yet even here we do not find such a graduated series" It can only be concluded that she has not held in her hands the series of ammonites from *Liparoceras* through *Androgynoceras*, *Amaltheus* to *Pleuroceras*, demonstrated by L F Spath, nor the series of *Micraster* demonstrated by D Nichols As for the series of horses, Dr Himmelfarb's information is not more recent than that of T H Huxley in 1870 Actually the fossil series of ancestors of the horse is now so good that George Gaylord Simpson has been able to measure the time required for the conversion of a species into another and the length of life of a species (two million years in horses) T S Westoll had done the same for fish, which evolve at different rates Simpson was also able to show that the geological record in some places is so good that it is now possible to calculate the degree of variability of fossil species and to prove that it is not correlated with their evolution-rate This is further evidence that natural selection, not mutation, controls the rate and direction of evolution

The statement that the geological record is one of the most serious weaknesses of Darwin's theory is ridiculous Even in his day, the Mesozoic mammals of the Stonesfield Slate had been discovered, and that most beautiful of all known fossils, *Archaeopteryx*, was known, showing such a perfect transition between the reptilian and the avian stages of that line of evolution that it can be regarded as ancestral to all later birds It also demonstrates the way in which one vertebrate class become converted into another, by piecemeal transformation of bits of the body one by one, a process called mosaic evolution Other examples of representatives of precursors are *Jamoytius* between the lowest chordates and the fishes, *Ichthyostega* between fishes and amphibia, *Seymouria* between amphibia and reptiles, *Ictidosaurs* between reptiles and mammals, *Australopithecus* between apes and man All these, and countless others, are a striking vindication of Darwin's views

The sudden appearance in the geological record of representatives of important groups (such as the gastropods or vertebrates) is no fly in the ointment of Darwin's theory, and it receives a logical explanation from the obligatory rarity of tentative initial types, and from the principle of 'clandestine evolution' of young stages without hard parts and therefore not preserved as fossils until they became adult in their new state As for the abrupt appearance of fossils in "the lowest fossiliferous strata", the number of fossils discovered in Pre-Cambrian deposits goes on increasing and now includes algae and fungi in which eight amino-acids could still be recognized although they are 1,700,000,000 years old

Dr Himmelfarb states (p 310) that chemists showed that all the pieces of the 'Piltdown find' revealed the same fluorine content This was not the case The earliest estimations by K P Oakley and C R Hoskins showed fluorine percentages varying from 3 1 to less than 0 1, estimations correct to within a range of ± 0 1 This proved that all the 'specimens' were not Lower Pleistocene Subsequent estimations by more refined methods showed that the latest of these were not even Upper Pleistocene But if Dr Himmelfarb really thinks that the exposure of the Piltdown fraud "leaves the theory (of evolution), after a century of search, without the much desired link", *Proconsul, Australopithecus, Pithecanthropus* and Neanderthal man are there to bear witness to what Sir Wilfrid Le Gros Clark has demonstrated from them about the so-called 'much desired link'

If ever the cult of personality should attempt to invade science, it would cease to be science , and if scientists hold Darwin in honour to-day, it is because the evidence, all the evidence, and nothing but the evidence provided by the observations and experiments of biologists who have undertaken research in this field, has shown that the natural selection of mutant and recombined genes is the mechanism whereby the evolution of plants and animals in Nature has been brought about

GAVIN DE BEER

THE FAITH OF A REALIST

Blaise Pascal

The Life and Work of a Realist By Ernest Mortimer Pp 240+4 plates (London Methuen and Co , Ltd , 1959) 21*s* net

MUCH of Pascal's work, and several books about him, are readily available what is not so easy to obtain is an assessment of his place in history in keeping with the pedestal upon which his fellow-countrymen are nearly unanimous in placing him Furthermore, to find an answer to the question as to how much he means to us to-day is assuredly a rewarding task These things the author has done and the result is a notable achievement Pascal emerges as a character of gigantic intellectual and spiritual stature , weak of body, indomitable of will, and relentless in his quest for truth

In the present context, we may perhaps leave aside the well-known facts of his mathematical genius, his contacts with great minds like those of Descartes, Fermat and Desargues, and concentrate upon his theory of knowledge (Chapter 11), which developed from the intense strife going on within him, and which burnt itself out as a consuming fire Pascal was no mere dreamer, but on the contrary passionately concerned with making things work His technical skill, if he were alive to-day, would lift him to the summit of electronic computing, and to the highest triumphs of cybernetics and servo-mechanisms In this sense, he was a realist , his faith transcended it, however, as he reached out towards that greater truth only to be found in charity

It is from some such position as this that we can best approach Mr Mortimer's treatment of Pascal's theory of knowledge, for it is essentially here that the present volume finds much of its *raison d'être* Here too is Pascal's message for the world to-day

The central concept is that of *le cœur* By this Pascal did not envisage something "cardiac rather than cerebral" He uses the phrase to cover a species of synthesis, a type of thought in which analysis gives place to cognition It seems as if this came out of a state of mind akin to despair, in that, for example, the propositions of Euclid needed acceptance of something "given" before any progress could be made, and thus real knowledge could never be obtained In this, he was in effect anticipating Godel s theorem, and the failure of Hilbert to construct a consistent system of mathematics purely mathematically But for Pascal, truth is not apprehended by reason alone, which can only yield statistical properties

Mr Mortimer is at pains to point out that Pascal did not draw this inference himself , it is nevertheless the gist of his whole argument Here indeed is a startling preview of twentieth-century science, quantum theory, operationism and all Nevertheless, the part to be played by *le cœur* remains, and it stands supreme if we are to 'know' the world around us But what is it, if it is not rational knowledge ? Pascal gives his answer—"Le cœur a ses raisons, que la raison ne connait point" Metaphysics may be out of fashion at the moment it looks, however, as if the faith of a great realist may have elevated such a discipline to a position otherwise unheeded

As people exclaimed in another setting altogether, "We have seen strange things to-day" The author has written a book modest in compass but great in concept He has brought Blaise Pascal, his tempests stilled at the last, into the centre of contemporary thought

F I G RAWLINS

ENZYMES—KINETICS AND CHEMISTRY

Behavior of Enzyme Systems

An Analysis of Kinetics and Mechanism By John M Reiner Pp xii+317 (Minneapolis, Minn Burgess Publishing Company, 1959) 6 50 dollars

Proceedings of the International Symposium on Enzyme Chemistry

Tokyo and Kyoto, 1957, organized by the Science Council of Japan under the auspices of the International Union of Biochemistry (I U B Symposium Series, Vol 2) Pp 541 (Tokyo Maruzen, 1958) n p

LET Dr Reiner speak for himself In his foreword addressed to "Timid Souls" he writes, "The foremost purpose of this book, accordingly, is To make it possible for anyone to begin the book knowing substantially nothing, and to finish it an expert for all practical purposes" This is a bold ambition, even when restricted to the field of enzyme kinetics A major adverse criticism of this book is, in the reviewer's opinion, the almost complete lack of reference to published experimental work , one has to turn many pages before one can see even the name of an enzyme and there are virtually no numerical data given Dr Reiner's ideal reader, the ignorant but intelligent man, but one, nevertheless, longing to learn, would find himself bewildered by reality Putting these criticisms aside, this book is a serious piece of scholarship, and provides a useful introduction to the theory of enzyme kinetics

In contrast to Dr Reiner's solo performance, the Proceedings of the International Symposium on Enzyme Chemistry, relating to a conference which took place in Tokyo and Kyoto in October 1957, contains contributions from 228 authors Apart from four special lectures delivered by Profs Chance ("Cytochromes—their Nature and Function in Living Cells"), Engelhardt ("Enzymology and Mechanochemistry of Tissues and Cells"), Lynen ("Phosphatkreislauf und Pasteur-Effekt") and Tamiya ("The Koji, an Important Source of Enzymes in Japan"), the Proceedings are divided into four sections

The first section covers the mechanisms of enzymatic group transfer, the second, enzyme systems of hydrogen, oxygen and electron transport, the third, the formation of proteins and enzymes, and the fourth relates to enzymes and industry (interpreted to include pharmacology) Many of the contributions are, in effect, short reviews (2–10 pages) of specialized topics, supplemented with what was in 1957 new experimental material. These articles are, in general, of a high standard and are, in the main, very readable

The title given to the Conference in no way restricted the range of topics , enzyme chemistry was taken to include any reaction catalysed by enzymes in animals, plants and micro-organisms Papers dealing with the action of thyroxine on isolated animal mitochondria and the role of chlorophyll in photosynthesis occur in the same section

The majority of contributions are in English, a few in German and even fewer in French Almost inevitably some of the papers, from veterans of international conferences, have appeared in substantially the same form before or since

J B Chappell

CHEMISTRY OF PHOSPHORUS

Phosphorus and Its Compounds

By John R Van Wazer Vol 1 Chemistry Pp xiii+954 (New York Interscience Publishers, Inc , London Interscience Publishers, Ltd , 1958) 208*s*

THIS volume must be unique, for it gives in wide scope and considerable detail an account of the structure, the physical and chemical properties, and the chemical reactions of phosphorus and all its main classes of compounds, both inorganic and organic It is also outstanding, not only for the wide range of the modern scientific information which is so clearly presented, but also for the historical background of this information each main topic has a historical introduction, so that, for example, the discussion of the structure of one class of compound may range from a brief review of the theories of a century ago to a more detailed discussion of the most recent evidence supplied by nuclear magnetic resonance spectra

The first two chapters deal respectively with the nuclear and atomic structure of the phosphorus atom, and with interaction between atoms the second chapter discusses in detail bond-energies and lengths, dipole moments, polarity of molecules, ionic radii, etc The following chapters discuss in turn various classes of phosphorus compounds The detailed information available may be assessed from the 380 pages devoted to phosphoric acid and its compounds, divided into five chapters on condensed phosphates, orthophosphoric acid, chain phosphates, ring and branched phosphates and amorphous phosphates, respectively This treatment ranges in these five chapters from the physical and chemical properties of phosphate minerals on one flank to those of the nucleic acids on the other Throughout the book the constant comparison of the properties of the purely inorganic compounds of phosphorus and those of their organic substitution products makes fascinating reading, and may well serve both to widen and to readjust the mental balance with which inorganic and organic chemists have hitherto in their different ways assessed the chemistry of phosphorus

In the preface, the author makes an eloquent plea that the present division of descriptive chemistry into two parts, organic and inorganic, should now be widened to include a third part, namely, phosphorus chemistry Many chemists will shrink from this suggestion, but it must be admitted that although phosphorus chemistry contains, on one hand, a number of reactions which can be regarded as normal reactions of inorganic compounds, and on the other hand many reactions typical of organic compounds, there lies in the centre a host of reactions and aspects of behaviour which are peculiar to phosphorus The same statement might possibly be made of the chemistry of every non-metallic element, but the specific chemistry of phosphorus is, in its range and nature, much greater than that of any other element except carbon This quality is one of the major factors underlying the vast increase in the academic and technical interest in phosphorus chemistry which has occurred during the past twenty years

The price of this book may appear high by English standards, but the volume contains an immense amount of information, liberally illustrated by X-ray structure diagrams, phase-rule diagrams, etc , and by a wealth of valuable tabulated material The final three appendixes list in turn phosphate minerals (40 pages), giving details of each, based largely on Dana's 'System of Mineralogy" , single bond energies and distances with electronegativity differences , and thermodynamic data on the compounds of phosphorus

The book, however, is emphatically not a mere catalogued compilation of facts In spite of the size of the book, the author has maintained to the end a critical treatment of the material under discussion, and this treatment, combined with the author's pleasant and lucid style, gives the book a personal flavour which heightens the reader's interest throughout the volume

The publishers are to be congratulated on the general format and printing of the book, and in particular for printing references at the bottom of pages, where they can be immediately noted by the reader, instead of printing them in a vast huddle at the end of each chapter

The book will be appreciated by all types of chemist, inorganic, organic, physical and phosphoric

Suggestions to Authors of the Reports of the United States Geological Survey

Fifth edition Pp xii+255 (Washington, D C Government Printing Office, 1958) 1 75 dollars

IN the eighty years that have passed since the foundation of the United States Geological Survey, more than 3,500 volumes of scientific and technical literature and more than 20,000 different maps have been published under its auspices—an output far surpassing that of any other geological institution in the world Throughout this long history, continuous efforts have been made to promote lucidity, consistency and uniformity in these publications, and the code of practice established by the Survey for its authors, first published in 1909, has found widespread use outside official circles The much enlarged fifth edition of this manual outlines the successive literary steps which a geologist-author will normally take from the beginning of an investigation to the final proof-reading of his text, maps and illustrations It advises on matters of ethics and professional etiquette, enumerates the requirements of a well-prepared manuscript, deals at length with questions of typographical style, and gives a great deal of detailed information on the form and content appropriate to reports of various kinds More than 50 pages are taken up with sensible advice on composition and expression, forming a sort of "A B C of Plain Words" directed specifically at geologists Not all the suggestions will be acceptable to British readers, who may be somewhat puzzled by the preferred use of 'geologic' and comparable '-ic' endings in a country with a Geological Survey and a Geological Society But there is no similar guide produced on the eastern side of the Atlantic , and, with appropriate warnings, the work could profitably become prescribed reading for all post-graduate students of geology, as a brake on the present over-production of 'geologese'

C. F DAVIDSON

Causes de la Répartition des Etres Vivants

Paléogéographie, Biogéographie Dynamique Par Raymond Furon (Evolution des Sciences, No 10) Pp 168 (Paris Masson et Cie , 1958) 1,000 francs

THIS book is well described by its author, in his preface, as "ce petit livre de 'morceaux choisis' n'est donc dans mon esprit qu'une esquisse de ce que pourrait être un beau livre qui n'existe pas un Traité de Biogéographie", for it touches upon almost every aspect of its subject Unfortunately the touch is too light to permit the suggestion of solutions to the many problems it describes, and this almost inevitably excites, rather than calms, the doubts that haunt most biogeographers as to whether the chaos of facts with which they are confronted can ever be reduced to final order

Moreover, so vast a subject can be compressed within the limits of a single short book only by the most careful and balanced selection of information, and of the sources from which this comes, and in this respect also the book leaves more than a little to be desired

With the author's main conclusions, that the present distribution of organisms chiefly reflects the catastrophic consequences of the Pleistocene glaciations, and that to understand the history of the living world its distribution in the Tertiary must be reconstructed, few biogeographers will disagree They are likely to agree also that palæogeography and palæontology are the keys to this reconstruction, but they are likely to feel some disappointment that an author so well qualified to comment on these particular aspects of the matter does not give a clearer lead as to how they may be more profitably pressed into service

The great value of the book is as a source of much useful, and not infrequently unusual, factual information, and as such it can be recommended to all who are interested in the distribution of plants and animals

RONALD GOOD

Die Banderschnecken

Eine Studie zur Evolution der Tiere Von Prof Dr F A Schilder und Dr Maria Schilder Schluss Die Banderschnecken Europas Pp iv+93–206 (Jena Gustav Fischer Verlag, 1957) Broschiert, 30 30 D M

IN this third and final part of their monumental work on polymorphism in the banded snails (*Cepaea*), Prof F A and Dr Maria Schilder have tried to give an account of the variation in all parts of the ranges of the four species, and to draw some evolutionary conclusions The booklet contains much useful information but suggests that such a task requires many more workers The maps summarizing the data may be adequate for some areas of Germany, but it is well known that the proportions of the different colour and banding forms can vary greatly between adjacent colonies , for some large areas far too few colonies have been investigated for any reliance to be placed on mean frequencies from them as truly representative

The conclusion reached is that the different forms in the polymorphisms have spread out from centres of special abundance Lamotte's work is quoted as proving that visual selection by predators can never be of importance The authors seem unaware of published criticisms of both Lamotte's conclusions, which are certainly invalid for Britain, and of their own inferences from their previous work on *Cepaea* They combine data from colonies for making inferences about selection, although some at least of those colonies are in disturbed habitats and certainly not in genetical equilibrium with their environments The composition of such colonies in relation to their habitats need give no indication that selection of any sort is acting, even though in fact it may be very strong The data are given only to the nearest 10 per cent, and are too inaccurate for re-working

A J CAIN

The Sea-Horse and Its Relatives

By Gilbert Whitley and Joyce Allan Pp ix+84 (Melbourne Georgian House, Pty , Ltd , 1958) 30*s* net

APART from a cosy introductory chapter which oozes with unsubstantiated sentimentalities, Whitley and Allan's book will be of value to interested ichthyologists as well as the children for whom it is primarily intended Besides an account of the lore and legends of sea-horses, there are good descriptions of the structure, behaviour and reproduction of this remarkable fish which Sir J Arthur Thomson once described as the "most 'kenspeckle' creature of the sea" The systematics of the sea-horse show that about a hundred species have been recorded, and these are distributed over four genera About half the book is concerned with these and the rest with pipe-fishes, trumpet fishes, flute-mouths, bellows fishes and razor fishes These, like the sea-horses, are illustrated by some remarkably fine drawings, most of which have been prepared by the authors

T H HAWKINS

RADIATION OBSERVATIONS WITH SATELLITE 1958δ OVER AUSTRALIA

By Dr A J. HERZ, Dr K. W OGILVIE and J. OLLEY

The F B S Falkiner Nuclear Research Laboratory School of Physics*, University of Sydney

AND

R B WHITE

Radio Research Board, Commonwealth Scientific and Industrial Research Organization, University Grounds, Sydney

IN June 1958 the School of Physics of the University of Sydney received a cabled request from the Academy of Sciences of the U S S R asking for help with the recording of signals from *Sputnik III* (1958δ2) As a result of this request, signals from many transits during July and August were recorded with equipment kindly put at our disposal by the Radio Research Board of the Commonwealth Scientific and Industrial Research Organization

Unfortunately, details of the instrumentation aboard the satellite and of the code used did not reach us until late September 1958, and even now we do not have all the information needed for a complete analysis of the data We believe, however, that our results are of sufficient interest to be reported at this stage

Description of Apparatus

It is now well known[1,2] that among the equipment carried by *Sputnik III* is a scintillation counter Because of the large size of the crystal (a cylinder of sodium iodide, 40 mm high and 39 mm in diameter), the detection efficiency for low-energy photons is high, and fast charged particles give very large pulses, corresponding to the loss of several MeV or more In particular, the counter responds with high efficiency to bremsstrahlung photons emitted as the result of the absorption of electrons with energies of about 100 keV which collide with the sputnik

A block diagram of the photon counter and its associated telemetering apparatus is shown in Fig 1, and Fig 2 gives the pattern of the signals The second and third pulses carried the information from the scintillation counter We do not know what information the first pulse carried

Fig 1 is largely self-explanatory The anode current of the photomultiplier is integrated and fed to a bistable circuit which switches relay *A* at intervals corresponding to a loss of energy in the crystal of 2 × 10^9 eV [1] The current to the seventh dynode similarly controls relay *C*, which switches at intervals corresponding to an energy loss of 18 × 10^9 eV In addition, the last dynode was connected to a scaler which controlled the switching of relay *B*

Table 1 Positions of 1958δ2 during Observations

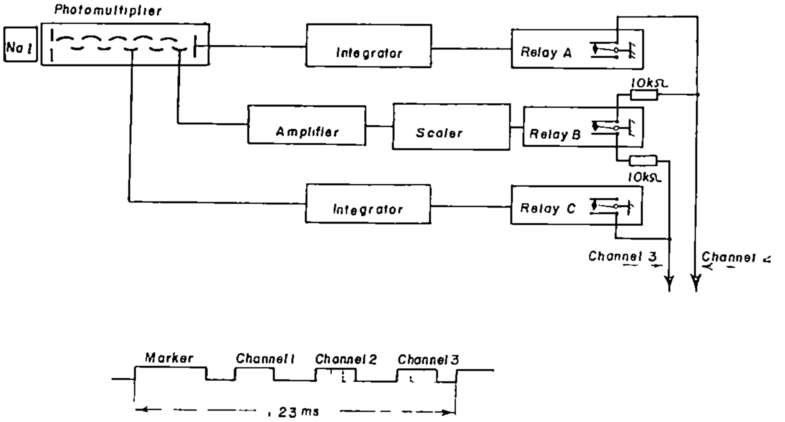
Epoch		Time (U T)	Altitude (km)	Latitude	Longitude
July 19	86806	2050	1,805	26 8° S	148 9° E
July 19	87431	2059	1,753	47 9° S	163 7° E
July 23	81250	1929	1,798	23 0° S	151 8° E
July 23	81389	1932	1,807	27 9° S	153 7° E
July 30	74514	1753	1,794	20 6° S	146 5° E
July 30	74861	1758	1,800	32 9° S	153 5° E
Aug 4	70556	1656	1,792	27 3° S	146 9° E
Aug 4	70764	1659	1,780	34 6° S	150 9° E

At the time our observations were made, the scaling circuit had ceased to operate so that relay *B* remained in a fixed position throughout So channel 2 (the second pulse) transmitted information about the position of the anode-current relay *A*, and channel 3 about the seventh-dynode-current relay On most of our records the marker and the first-channel pulse are missing as part of the modulating equipment was operating only intermittently, but the data given in this report are all taken from records in which all the pulses are present

Positions of the Satellite during Observations

The positions of 1958δ2 used by us were calculated with the aid of the elements of the orbit published by the Smithsonian Institution, and with an orbital period found from a least-squares fit to the transits observed at Sydney

The results of these calculations are given in Table 1 and displayed in Fig 3



Figs 1 (above) and 2 (below)

---

* Also supported by the Nuclear Research Foundation within the University of Sydney

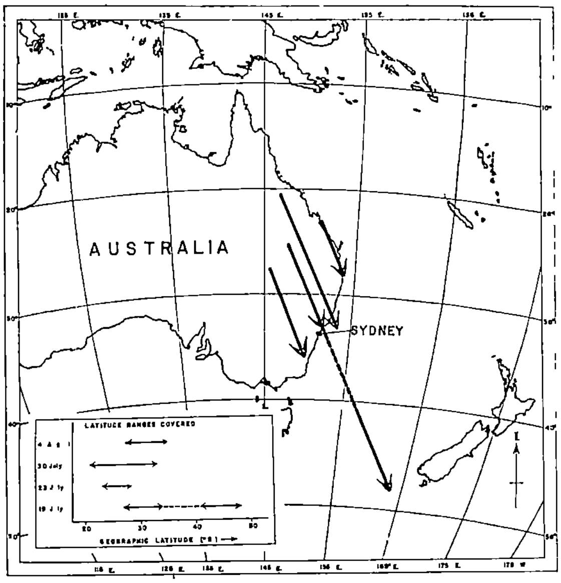


Fig 3

Results and Conclusions

The rates of energy loss in the crystal during our five recording periods are plotted as function of time (U T) in Fig 4 Combining these with the positions of the satellite (Fig 3 and Table 1) we find a minimum of radiation intensity at a geographic latitude of about 35° S The intensity appears to increase by an order of magnitude when the latitude changes by approximately ten degrees on either side of this minimum Similar observations over Australia, made with satellite 1958ε (*Explorer IV*), have been reported by Van Allen *et al* [3], who suggested that these minima correspond to outward-projecting 'horns' in the contours of constant radiation intensity The minima can presumably be interpreted as the gap between the inner and outer radiation belts which have recently been discovered by means of the Russian artificial planet[4] and by Van Allen and co-workers using the American lunar probes

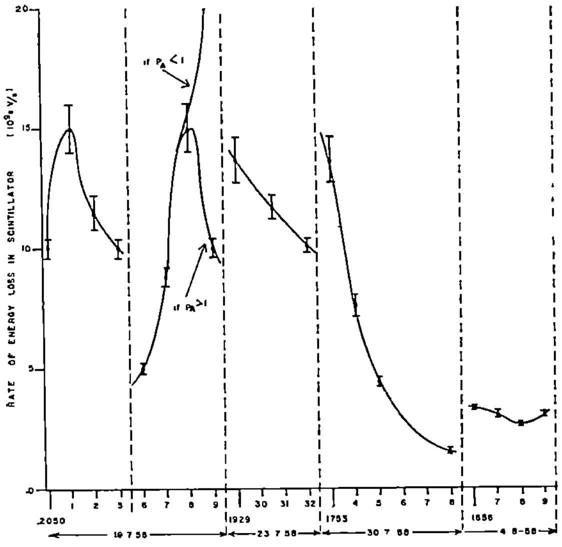

Fig 4

Our data also suggest a time variation in the radiation intensity the mean intensity during the first part of the transit of July 19 (see Fig 4) is about five times the mean for August 4 although the satellite moved through almost exactly the same region in the two cases We do not know whether the distribution of absorbing matter around the scintillator is such that tumbling of the sputnik could cause such large fluctuations , but, in any event, we do not believe that the fluctuations are so caused since our observations of the signal strength suggest a tumbling period not greater than about 40 sec — much less than our intervals of observation

We tentatively conclude that the intensity of radiation in the region observed may show very considerable variations with time This may be of particular significance as the region in question straddles the gap between the two radiation belts

Our remaining conclusions concern the ratio of the switching rates of relays *A* and *C* It appears to us that the telemetering equipment was not designed to handle the high switching rates, especially of relay *A*, which corresponds to the intensities of radiation encountered by the satellite The switching rate of relay *A* almost always overloaded channel 2 during our periods of observation We were, however, able to obtain adequate data on the rates of loss of energy through channel 3—these are the ones plotted in Fig 4

When a large charge passes through the later stages of a photomultiplier, its anode-current response becomes non-linear, and for extremely large flashes of light the current from the dynodes also becomes a non linear function of the light input The ratio of the switching rates of relays *A* and *C* therefore depends on the average magnitude of the light flashes at low counting rates, and on the average light output from the scintillator at counting rates so high that the interval between the individual events in the crystal is less than the decay time of the light pulses (about 5 μsec in sodium iodide) According to Vernov *et al* [1] the ratio of the switching rates of relays *A* and *C* is 9 1 if the photomultiplier operates in the linear region of its response curve , it will be less if an appreciable number of the pulses is caused by particles which lose large amounts of energy in the crystal, and it will also be less if the number of photons detected in unit time is extremely large

It was therefore of interest to try to find values for the switching rate of relay *A*, and we were able to do this as we explain in detail below The results show that the ratio of the switching rates was of the order of 4 1, with fluctuations in the range 3 8 1 to 6 1 Individual results are shown in Table 2 , they suggest that the ratio decreased with time As we have no information about the response curves of the apparatus we cannot draw conclusions about the nature of the radiation from this

Table 2 THE RATIO p_C/p_A

Epoch	Time (U T)	p_C/p_A
July 19 86806 to July 19 87431	2050 to 2059	5 0 ± 0 3
July 23 81250 to July 23 81389	1929 to 1932	4 4 ± 0 1
July 30 74514 to July 30 74861	1753 to 1758	3 9 ± 0 2
Aug 4 70556 to Aug 4 70764	1656 to 1659	3 0 ± 0 2

Recording Method

The receiving aerials were two horizontal dipoles placed at right angles to each other Each dipole

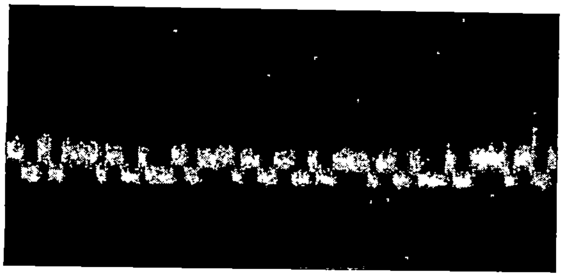

Fig 5

fed a communications receiver, and the rectified signals from the second detectors were further amplified by two separate d c amplifiers The two outputs were then summed by a resistive mixing network and the resultant was applied to the deflecting plates of a cathode-ray tube The spot was photographed on 35-mm film moving perpendicular to the direction of deflexion at a speed of 0 6 in /sec (1 52 cm /sec)

Characteristics of the Signal

A sample of one of our records, showing complete pulse trains with marker pulses and first pulses, is given in Fig 5 The pulse-lengths were measured with the aid of a travelling microscope A sample of a pulse-length distribution (for the transit of July 23) is shown in Fig 6

The various combinations of positions of relays *A*, *B* and *C* lead to pulses of nominal lengths 50, 100 and 150 μsec [1] which we designated 'short', 'medium' and 'long' As the position of relay *B* was fixed, the second-channel pulses were either long or short, depending on the position of relay *A* only, and the channel-3 pulses were of either short or medium length It is clear from Fig 6 that in both channels there occurred a number of intermediate-length pulses these were caused by the switching of a relay while a pulse is being transmitted

With the aid of time markers recorded on the film we were able to measure the pulse-lengths The results are given in Table 3

Table 3 LENGTHS OF PULSES AND PULSE TRAINS

	Nominal value* (m sec)	Measured (m sec)
Short pulses	50	69 ± 8
Medium pulses	100	115 ± 8
Long pulses	150	161 ± 10
Pulse train including marker	1,230	1,210 ± 30

* Vernov *et al* (ref 1)

Analysis of the Records

In the system of telemetering used, the positions of the relays are sampled at regular intervals of 1 23 sec (the cycle-length) A change in the length of the appropriate pulse occurs whenever the number of switchings during the preceding cycle was odd, no change is found when the number of switchings was even If a relay is switched during transmission of the pulse the length of which it controls, a pulse of intermediate length occurs

If the relay is switched at intervals which are large compared with the length of the sampling cycle, every switching results in a change of pulse-length Common sense suggests that the converse is also true that changes in pulse-length at intervals large compared with the cycle-length denote an equal number of switchings, each of which occurred during the cycle immediately preceding the change Although not strictly true, as we shall see below, this turns out to be almost always correct

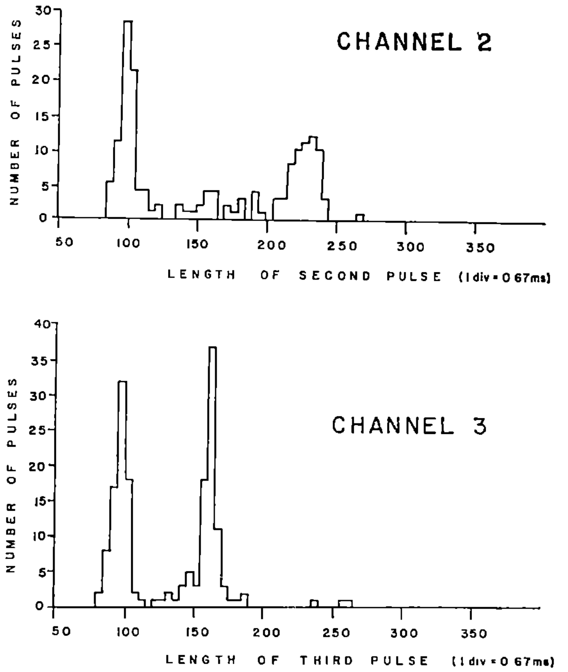

Fig 6

For more detailed analysis we plot (Fig 7) the interval between pulse-length changes as a function of the interval between switchings of the relay It is clear that if the interval between switchings were really constant, and if there were no additional information, we should not be able to deduce a unique value of the switching frequency from the observations of changes in pulse-length Fortunately, however, the intervals fluctuate, and we have other data as well

The published information shows that if the photomultiplier is working in the linear region of its anode-current characteristic, the ratio between the switching rates of relays *A* and *C* is 9 1 Overloading cannot increase this ratio, so that we accept only those pairs of switching rates which have ratios of 9 1 or less Secondly, as Fig 7 shows, the lengths of the intervals between changes are very sensitive to changes in the switching rate when there is more

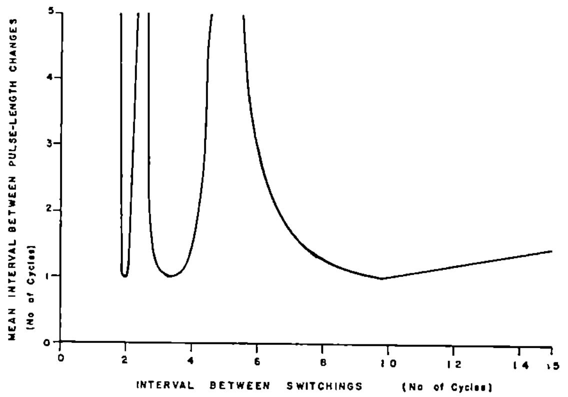

Fig. 7

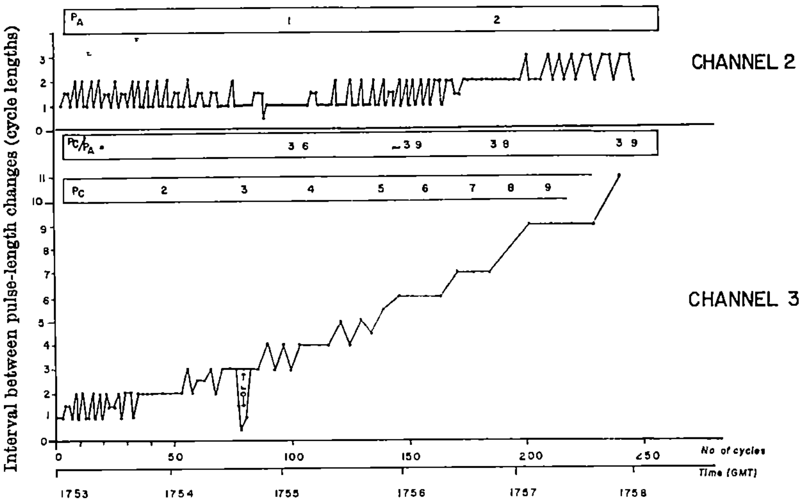

Fig 8 July 30, 1958 1753–58 G M T

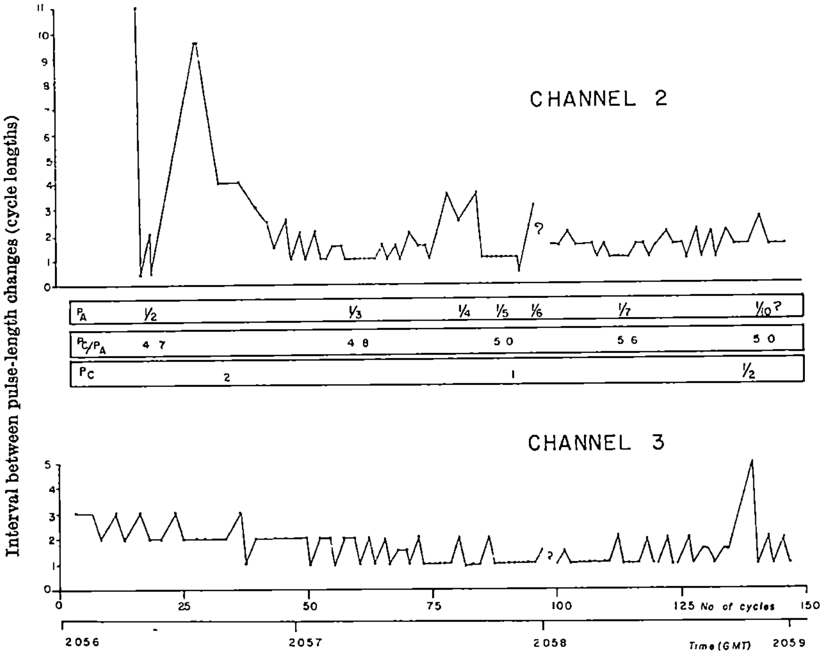

Fig 9 July 19, 1958 2056–59 G M T

than one switching per cycle In the presence of fluctuations it is thus quite unlikely for high switching rates to give rise to long successions of pulses of equal size, that is, to consistently long intervals between changes in pulse-length We conclude that if the intervals between pulse-length changes are consistently longer than the sampling cycle, the frequency of the changes is equal to the switching frequency of the relay concerned During most of our observation time the less-sensitive channel 3 operated in this way so that we could deduce the radiation intensity directly from the frequency of pulse-length changes in it

With one exception, at 1758 U T on July 30 (see Fig 4), the intervals between the switchings of relay A in channel 2 were always less than the length of the sampling cycle The intervals between pulse-length changes thus rarely exceeded two cycles, and we could not obtain information about the rate of switching from the average magnitude of these intervals alone However, for the reasons discussed earlier we felt it worth while to try to estimate the switching frequency of relay A

The possible values of the interval p between switchings can be obtained from Fig 7, and the smaller values of the intervals p_A (between the switchings of relay A) can usually be eliminated because of the requirements that the ratio p_C/p_A cannot be greater than 9 1 In most cases we were still left with several possible values of p_A from which a choice had to be made using the patterns of pulse sizes in both channels

Two additional pieces of information helped us here First, the ratio of the switching rates is not likely to show violent discontinuous changes Secondly, in spite of fluctuations, there will be a brief series of equal-width pulses (no changes) whenever the number of switchings per cycle is nearly equal to an even integer ($p = 1/n$ cycle lengths where n is even) Whenever there is an odd number of switchings per cycle there will be a series of pulse-length changes every cycle This effect, though not very pronounced, is clearly observable

In our analysis we used a graphical method of display, of which we show examples in Figs 8 and 9 Along the horizontal axis we plot the times of occurrence of changes in pulse-length, while the ordinate gives for every change the time elapsed since the immediately preceding one We also indicate on the diagrams our estimated values of p_A and p_C and of the ratio p_C/p_A The intervals p are measured in units of one cycle-length

Fig 8 shows the record corresponding to our lowest detected radiation intensity the only case when we found p_A to be undoubtedly greater than unity It can be seen clearly that p_C/p_A is approximately equal to 3 8—much less than the nominal value 9

Fig 9 is a display of data from an observation period during which the radiation intensity was high and changing rapidly According to our estimates, p_A varied from approximately 1/2 cycle to 1/10 cycle during the time covered by the diagram, and the record shows particularly clearly the peaks in the plot associated with even integral values of $1/p_A$, and the runs of pulse-length changes every cycle which occur when $1/p_A$ is odd

We should like to thank Prof. H. Messel for the excellent laboratory facilities made available to us, and Dr. G. H. Munro, the officer in charge of the Sydney Section of the Radio Research Board, for making possible the recording of the sputnik transmissions. To Academician L. I. Sedov we are grateful for an informative discussion during his recent visit to Australia, and for the reprints he presented to us. We are much indebted to Miss Xenie Federoff for the careful and conscientious way in which she carried out the tedious work of reading the records. One of us (J. O.) would like to thank the Commonwealth Scientific and Industrial Research Organization for the award of a studentship.

ROBERT HOOKE AND BOYLE'S AIR PUMP

By Dr. H. D. TURNER
University of Sheffield

It is just three hundred years since Robert Hooke built Boyle's air pump. This event has been described by Gunther[1] as "the most important research ever brought to a successful issue in Oxford"; and it is perhaps appropriate to mark the tercentenary by examining the truth of this statement and, incidentally, by somewhat belatedly giving Hooke the acknowledgment which is his due for his share in the enterprise.

Robert Hooke, who was born on July 18, 1635, at Freshwater in the Isle of Wight, was the son of the local curate. He was a sickly child and never robust, but he gave early evidence of that mechanical aptitude which led to his being described as "certainly the greatest mechanick this day in the world"[2]. After the death of his father, Hooke went, at the age of thirteen, to Westminster School; and in 1653 he went to Christ Church, Oxford, as a chorister, being admitted to the degree of Master of Arts in 1663. During the latter part of his stay in Oxford, Hooke was employed as a laboratory assistant by Boyle, and in 1659 he built the air pump shown in Fig. 1.

At this time Boyle was very much interested in the mechanical properties of the air, and very dissatisfied with the behaviour of the air pump then available, that due to Otto von Guericke. In 1660 Boyle wrote his famous treatise on the "Spring of the Air"[3]. In this book, which was dedicated to his nephew, Lord Dungarvan, he says:

"As few inventions happen to be at first so compleat, as not to be either blemished with some deficiencies needful to be remedied or otherwise capable of improvement: so when the Engine we have comes to be more attentively considered, there will appear two very considerable things to be desired in it.

"For first, the *Wind Pump* (as somebody not improperly calls it) is so contriv'd that to evacuate the Vessel, there is required the continual labour of two strong men for divers hours. And next, (which is an imperfection of much greater moment) the Receiver or Glass to be employ'd, consisting of one entire and uninterrupted Globe and Neck of Glass; the whole Engine is so made, that things cannot be convey'd into it, whereon to try Experiments. So that there seems but little (if anything) more to be expected from it, than those very few *Phaenomena* that have been already observed by the Author and recorded by SCHOTTUS".

Boyle then goes on to say that he asked Hooke to contrive a more effective air pump.

"Wherefore to remedy these Inconveniences, I put both Mr. G(RATORIX) and R. HOOK (who hath also the honour to be known to your Lordship, and was with me when I had these things under consideration) to contrive some Air Pump, that might not like the other, need to be kept under water (which on divers occasions is convenient) and might be more easily managed. And after an unsuccessful tryal or two of ways propos'd by others, the last named Person fitted me with a Pump, anon to be

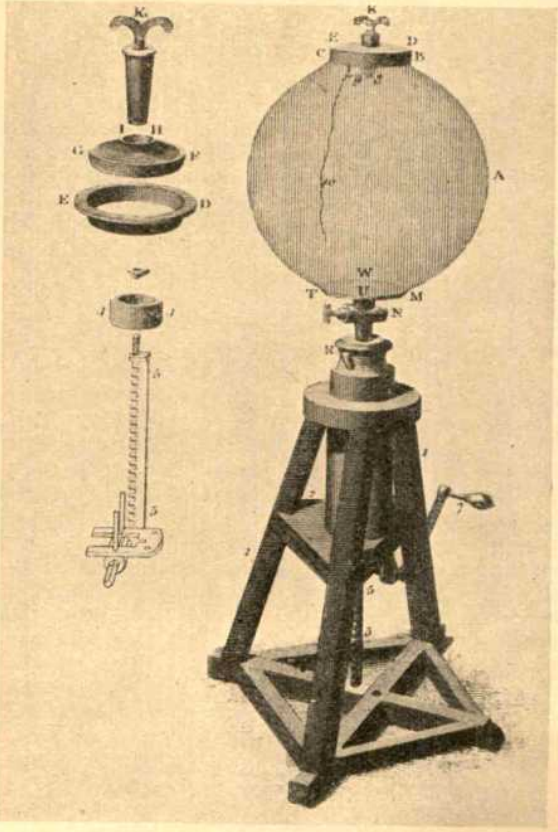

Fig. 1. Boyle's air pump, built for him by Robert Hooke in 1659. This was a notable advance on O. von Guericke's pump since the evacuated enclosure was easily accessible and the ratchet system enabled one man to operate the pump without undue effort. Hooke later built a double-acting pump which was even more effective and flexible in operation

described. And thus the first imperfection of the German Engine, was in good measure, though not perfectly remedied".

The cylinder of the pump was bored in London; but the rest of the machine was constructed by Hooke in Oxford. The technical difficulties were evidently enormous. Boyle goes on to say:

"Your Lordship will, perhaps, think that I have been unnecessarily prolix in this first part of my Discourse. But if you had seen how many unexpected difficulties *we* found to keep out the external Air, even for a little while, when some considerable part of the internal had been suck'd out, you would peradventure allow that I might have set down more circumstances than I have, without setting down any, whose knowledge, he that shall try the experiment, may not have need of".

Once an efficient air pump was available, there were many experiments which could be performed. One of the first investigations carried out by Boyle was into the relationship between the pressure and volume of a gas.

This led to the enunciation of 'Boyle's Law' or 'Boyle and Mariotte's Law' after its confirmation by Mariotte in 1676. Although Boyle does not explicitly name Hooke as his assistant and collaborator in this work, Gunther[4] believes that he was. At this time Boyle was suffering from weakness of eyesight; and he also complained of a lack of skill in geometry which made him "both unwilling and unfit to engage in any Study where the conversing with Mathematical Schemes is necessary". The suggestion is that Hooke, a skilled experimenter and a very able geometer, was, in fact, mainly responsible for the enunciation and proof of Boyle's Law.

Hooke himself carried out many experiments with the air pump. In 1662, having been released by Boyle, he went to London as curator of experiments to the newly formed Royal Society. In this capacity he had to demonstrate different experiments two or three times a week for the delectation of the Fellows; and in many of these he used either the air pump, or the condensing engine, a compressor which he built in 1662–23. For example, in April 1663 we find Hooke experimenting with water freed of air which, according to Huygens, did not subside in a Torricellian tube; and later, air was removed from above and within water containing various fish to see which would die soonest.
